ABSTRACT

This report deals with the study of electrostatic waves in bounded hot plasmas and, except for a few dc measurements, is theoretical.

The study is broadly divided into two parts. The first section investigates waves in a diode system with no dc magnetic field applied. A dc analysis of the equilibrium plasma produced within a thermionic diode is undertaken to provide a basis for the rf analysis, and expected plasma densities in the diode are computed for a variety of practical situations. Electrostatic wave resonances in the diode are predicted by using the hydrodynamic model for the nonuniform plasma. The impedance of a uniform plasma diode is obtained by using a kinetic model of the plasma. This model enables us to take into account the end plate electron absorption loss, a process similar to that which causes end plate diffusion in the Q-machine. The absorption loss is found to have a large effect on the impedance of the diode.

The second part of the report deals with the study of guided waves along a cylindrical column of Maxwellian plasma in a magnetic field. A dc study of the plasma column is first conducted. Theoretical density and current profiles are obtained and are compared with the measured results. Since an rf analysis using a self-consistent dc solution is involved, the plasma column is approximated by a uniform plasma with a sharp boundary and no drift. To obtain the rf fields in such a column, a plane-wave solution for an infinite Maxwellian plasma in an applied magnetic field is first obtained. By superimposing infinitely many plane waves, the fields within the column are constructed, and by matching the appropriate fields at the boundary, a dispersion relation is derived.

The solutions to the dispersion relation reveal the existence of a new type of unstable waves. When only the electrons are assumed to respond to the electric field, the surface waves which propagate when $\omega_{ce} < \omega_{pe}$ are found to be unstable. When the ion motion is included, additional unstable surface waves are obtained whenever $\omega_{ci} < \omega_{pi}$. A study of the instability shows that it is due to finite Larmor radii effects and is driven by the transverse energy of the particles.

While the "electron" surface wave instability is relatively weak and can easily be stabilized by making $-c_e > v_{pe}$, the "ion" surface wave instability is found to be very strong, and the stabilizing condition of $-c_i > v_{pi}$ is not easily attained in high density plasmas such as those in fusion machines. Thus, the unstable ion surface waves may have a serious effect on the containment of the fusion plasma.

ACKNOWLEDGMENT

I would like to express my sincere gratitude to Dr. Heinrich Derfler for his valuable guidance and interest during all phases of this work. I am also indebted to Dr. Thomas C. Simonsen for his cooperation and assistance throughout the course of this study, to Professor O. Buneman for his valuable comments, and to Professor L. Moll for reading the manuscript.

My gratitude is also expressed to Mrs. Elaine Christensen for her expert help in preparing the manuscript.

Last but not least, I would like to express heartfelt thanks to my wife, Claire, for her untiring support and encouragement.

I. INTRODUCTION

The object of this study is an investigation of electrostatic waves in bounded hot plasmas. While the bulk of prior work on electrostatic waves is restricted to infinitely extended plasmas, our study emphasizes the effects due to finite plasma boundary. Originally we hoped to avoid complications due to instabilities by restricting our work to near equilibrium plasmas. Yet in the study of a perfectly Maxwellian magneto-plasma column, we discovered unstable surface waves which are due to finite Larmor radii effects.

Plasmas in perfect thermostatic equilibrium are generated inside a black body, and our work on the subject of equilibrium plasma generation and the waves in such plasmas is summarized in Section A below. A near equilibrium column of plasma is obtained in a magnetic field between electron and ion emitting end plates. Prior work on electrostatic waves in such plasma columns and our own work which lead to the discovery of unstable waves is summarized in Section B. A brief review of known instabilities in Section C places the newly discovered instability into proper perspective.

A. PLASMAS IN PERFECT THERMOSTATIC EQUILIBRIUM

Theory and interpretation of experimental data on plasmas often suffer because the deviations from equilibrium are not known exactly. A situation in which all of the constituents are in equilibrium may be found inside a black body. A study of the dc states of an equilibrium plasma bounded by thermionically emitting walls is undertaken in Chapter II. An earlier work by Nottingham¹ considers the diode geometry consisting of two parallel infinite walls emitting only electrons. In such a system the electron density within the diode space was found to be highly nonuniform and became very low at a distance of a few Debye lengths away from the wall. We show that under equilibrium conditions a small amount of ions emitted from a thermionic emitter can neutralize the electron space charge to form a plasma in the diode space. This is illustrated by computations based on diode walls made from pure refractory metals. The effects of enhanced ion emission from the walls due to the

introduction of alkali vapor in the diode space are also examined. Some experimental measurements for a sodium plasma are given and compared with the theoretical prediction.

Electrostatic waves within the equilibrium plasma diode are studied in Chapter III. The nonuniform sheath effects are investigated by means of the hydrodynamic model of the plasma. Previously the hydrodynamic model was used by Weissglas² and later by Parker³ to explain the Dattner⁴ resonances in a nonuniform plasma column. As opposed to these previous works on free boundary sheaths, our study is directed to the cathode sheaths bounded by an emitter.

In the second part of Chapter III we present a study of end plate loss effects by using a kinetic model of the plasma. The end plate losses are due to the same mechanism which causes end plate diffusion in a plasma column such as that produced in the Q-machine.⁵ When particles in the magnetized plasma column are absorbed by the end plate and re-emitted with different guiding centers, the net result is a diffusion of the particles away from the column. In the diode system consisting of infinite parallel planes, we are not concerned with diffusion, but the process of absorption and re-emission causes rf energy loss in the diode. An electron emitted from the wall acquires rf energy as it traverses the diode space, and the entire energy is lost as it is absorbed at the other wall. Previous work by Hall⁶ used kinetic theory in considering a plasma capacitor but assumed perfect reflection of the particles at the boundary and thereby neglected the end plate loss effects. In our study we include the absorption effect at the end plate, but because of the extreme complexity of kinetic analysis, we were able to study only the case of a uniform plasma in the diode space.

B. ELECTROSTATIC WAVES IN A PLASMA COLUMN

In a practical plasma the emitting plates are not infinite in extent. In fact, plasmas are often produced between two circular emitting plates which are separated by a distance several times greater than the plate radius. Confinement of the plasma in such a column is achieved by applying a magnetic field along the axis. A dc study of such a column of magnetized plasma is given in Chapter IV. Theoretical density and

current profiles are computed from an appropriate solution to the Boltzmann equation and a comparison is made with some experimental results. The study indicates that the plasma column may be approximated by a uniform plasma with a sharp boundary. To simplify the study of waves in the plasma column, it is essential to assume that the column is uniform.

In 1957 Gould and Trivelpiece⁷ used the cold plasma model to predict electrostatic wave propagation along a uniform plasma column such as the one shown in Fig. 1.1. The dispersion relations for cylindrically symmetric waves along such a column are shown in Fig. 1.2. When $\omega_c > \omega_p$, propagation is confined within two frequency ranges, $0 \leq \omega \leq \omega_p$ and $\omega_c < \omega < \sqrt{\omega_p^2 + \omega_c^2}$. Whether the plasma completely fills the waveguide or not, these passbands are unaltered as long as $\omega_c > \omega_p$. However, when $\omega_c < \omega_p$, filled and unfilled waveguides have different passbands. For the completely filled waveguide, the two passbands are $0 < \omega < \omega_c$ and $\omega_p < \omega < \sqrt{\omega_p^2 + \omega_c^2}$. When the plasma does not fill the waveguide, the upper passband is as before ($\omega_p < \omega < \sqrt{\omega_p^2 + \omega_c^2}$), but the lowest order mode of the low-frequency band propagates in the band $0 < \omega < \sqrt{(\omega_p^2 + \omega_c^2)/2}$ as shown by the dotted line. This particular mode is a

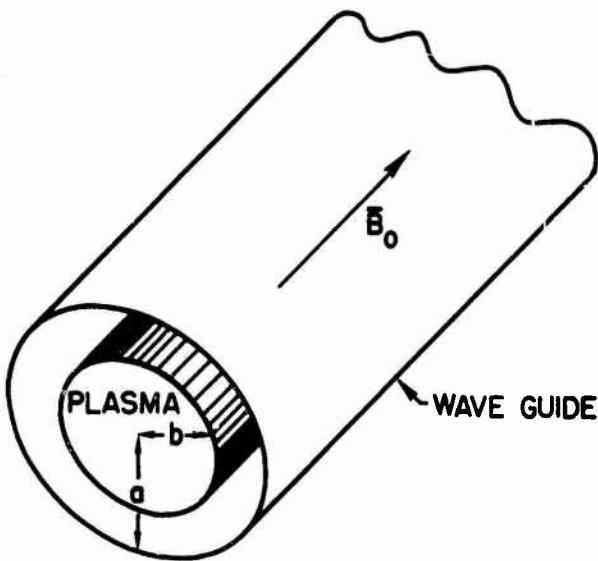

FIG. 1.1. CONFIGURATION OF PLASMA IN A CYLINDRICAL WAVEGUIDE.

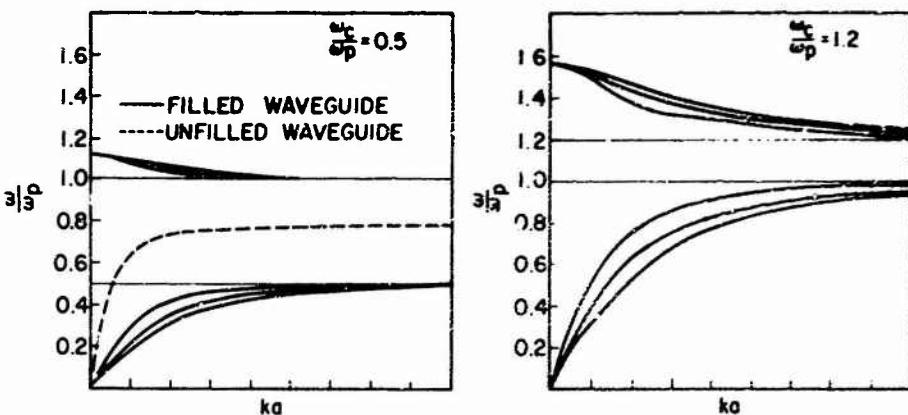

FIG. 1.2. DISPERSION RELATION FOR WAVES IN CYLINDRICAL PLASMA COLUMN. Dispersion relations for waves in a cylindrical column of cold plasma are given for two cases. The diagram on the right shows dispersion relations with $\omega_c = 1.2 \omega_p$ and on the left dispersion relations with $\omega_c = 0.5 \omega_p$ are shown. The quantity ka is the product of wavenumber and the waveguide radius.

surface wave in the frequency range $\omega_c < \omega < \sqrt{(\omega_p^2 + \omega_c^2)/2}$ in that the fields are strongest near the edge of the plasma. Such a surface mode cannot be excited in a filled waveguide. In Chapter VI attention is directed toward this surface wave which becomes unstable when the temperature effects are included properly.

Agdur and Weissglas⁸ used the hydrodynamic model of the plasma to point out the temperature effects. Later Jayson and Lichtenberg⁹ used an electron plasma model with Maxwellian velocity distribution along the magnetic field but with zero transverse temperature to compute dispersion relations for waves in filled waveguides. Kuehl et al¹⁰ used a fully thermal plasma model but with infinite magnetic field to compute the dispersion relation in the identical geometry. The models of Lichtenberg and Jayson and Kuehl et al yield Landau damping of the modes, while the hydrodynamic model does not. The study of waves in fully thermal unbounded magnetoplasma has been conducted by several authors,^{11,12} but the waves in a magnetoplasma column have not been treated before due to the extreme computational complexity involved. This paper reports the study of waves in a magnetoplasma column and the discovery of surface wave instabilities.

In preparation for the study of electrostatic-wave propagation in a magnetized plasma column, a dielectric tensor appropriate for an infinitely extended Maxwellian plasma is obtained in Chapter V. Our dielectric tensor is simpler than the "dielectric" tensor presented by Stix.¹³ The simplicity of our dielectric tensor results from subdividing the plasma current into polarization and magnetization currents. A cylindrical wave solution appropriate for a uniform column of Maxwellian plasma is synthesized from plane waves and the dispersion relation for the waves is obtained in Chapter VI. At low magnetic fields ($\omega_c < \omega_p$) the surface wave along the column of a Maxwellian electron plasma is shown to be unstable. The nature of the instability is studied by means of Derfier's stability criteria.^{14,15} The surface waves which occur near the ion cyclotron frequency when $\omega_{ci} < \omega_{pi}$ are also found to be unstable. Since the complete analysis is so vast, only the lowest-order cylindrically symmetric mode is numerically analyzed.

C. INSTABILITIES

Plasma instabilities can be divided into two general groups, microinstability and macroinstability. The instabilities which cannot be derived from the standard magnetohydrodynamic equations but which depend on detailed microscopic equations for the plasma are classified as microinstabilities. We are interested primarily in the microinstabilities which occur in a finite geometry.

Among the macroinstabilities in a current carrying plasma are the well-known kink and sausage instabilities which are caused by the interaction of the plasma with its self-magnetic field. Another instability which occurs in a plasma with a directed current is the Kadomtsev instability.¹⁶ The Kelvin-Helmholtz instability¹⁷ occurs in a stratified fluid in which the adjacent layers are in relative motion.

The above instabilities can be obtained from the fluid model of the plasma. The second class of instabilities, the microinstabilities, may be divided into two broad groups. The first are those instabilities which are caused by the peculiarities of the velocity distribution and may be called velocity space instabilities. The second group of instabilities depends on the plasma geometry. A simple example of the first

In preparation for the study of electrostatic-wave propagation in a magnetized plasma column, a dielectric tensor appropriate for an infinitely extended Maxwellian plasma is obtained in Chapter V. The dielectric tensor is simpler than the "dielectric" tensor presented by Sato.¹³ The simplicity of our dielectric tensor results from neglecting the plasma current, ionic polarization and magnetized currents. A cylindrical wave solution appropriate for a semi-infinite column of Maxwellian plasma is synthesized from plane waves and the dispersion relation for the waves is obtained in Chapter VI. A low magnetic field ($B_z \ll B_x$) the surface wave along the column of a Maxwellian electron plasma is shown to be unstable. The nature of the instability is studied by means of Debye's stability criteria.^{14,15} The surface waves which occur near the ion cyclotron frequency when $B_x = B_{z0}$ are also found to be unstable. Since the complete analysis is not feasible, only the lowest-order cylindrically symmetric mode is numerically analyzed.

C. INSTABILITIES

Plasma instabilities can be divided into two general groups, micro-instability, and macro-instability. The instabilities which cannot be derived from the standard magnetohydrodynamic equations and which depend on detailed microscopic equations for the plasma are classified as micro-instabilities. We are interested primarily in the micro-instabilities which occur in a finite geometry.

Among the macro-instabilities in a current carrying plasma are the well-known kink and sausage instabilities which are caused by the interaction of the plasma with its self-magnetic field. Another instability which occurs in a plasma with a directed current is the Kondratenko instability.¹⁶ The Kelvin-Helmholtz instability¹⁷ occurs in a stratified fluid in which the adjacent layers are in relative motion.

The above instabilities can be obtained from the fluid model of the plasma. The second class of instabilities, the micro-instabilities, may be divided into two broad groups. The first are those instabilities which are caused by the perturbations of the velocity distribution and may be called velocity space instabilities. The second group of instabilities depends on the plasma geometry. A single example of the first

type is the "two-layer mechanism" which occurs when charged streaming of charged particles occurs. In such a case streaming occurs due to there is temperature gradient in the plasma. Sato and Takemoto¹⁷ investigated the resistivities of a plasma with such temperature along the magnetic field but with non-uniformity reduced by the magnetic field structure. Their model can be applied upon to solving extreme temperature gradients.

The current was measured with contributions of the second group. While the magnetic field has contribution of magnetic pressure from the second group, velocity gradient is unimportant. Shultz studies of electric resistivity¹⁸ shows the most resistive part in both authors. Buschow and Ingard¹⁹ and Gurevich²⁰ independently demonstrated the so-called internal resistances which mean when there is a density gradient in the electric resistivity due to the magnetic field. This means, contributions arise because of resistance between the drift of particles in the management plasma and the drift velocities of the ions. Other papers by Gurevich²¹ and Buschow²² and Gurevich²³ and Tikhonov²⁴ present evidence and a more calculation of the ion drift frequencies in the electric resistivity plasma.

The surface wave dispersion which we discussed must also be considered in the second group when it is found that when the current gradient is finite. The surface wave dispersion is however is different from the one that we discussed. While the surface wave dispersion with the uniform distribution propagates in the direction perpendicular to both the density gradient and the magnetic field. The surface wave propagates along the magnetic field. In a cylindrical geometry with the density gradient in the field direction the wave with the uniform distribution must be at minimum, varying wave while the surface wave dispersion is found in the direction perpendicular to the field. Since it is the same condition with the helicity source distribution, the surface wave is not related to any of the helicity source distributions.

There is yet a third type of electron distributions which is a combination of the uniform space charge states and the permanent charge induced distributions. Post and Bremmer²⁵ discuss how a two-dimensional distribution is modified by a fixed density and magnetic field gradient. This effect can be again induce the surface wave dispersion.

II. DC STATES OF HOLLOW CATHODE PLASMA

Often plasmas produced in the laboratory differ from a true thermodynamical equilibrium plasma. In such nonequilibrium plasmas the energy distribution of the constituents (electrons, ions, neutrals and radiation) deviates significantly from Boltzmann's probability law ($\exp - E/kT$). These deviations are an apparently inexhaustible source for the discovery of new instabilities, designed by nature to ultimately restore equilibrium. Theory and interpretation of experimental data frequently suffer because the deviations from equilibrium are never known exactly. A situation where all constituents are as close as possible to strict thermodynamic equilibrium may be found within a boundary consisting of walls which thermodynamically emit electrons, ions, and neutrals. In this chapter we will examine the dc properties of equilibrium plasmas bounded by such thermodynamically emitting walls. Numerical results are given for some practical situations.

4. PLASMA DIODE

In this section we investigate theoretically the plasma produced between the two infinite plane emitting walls as shown in Fig. 2.1. There is no net dc potential across the diode, and the emitters emit electrons and ions in some known number ratio $\beta^2 = n_e(L)/n_i(L)$, which is fixed by thermodynamic considerations of the material.

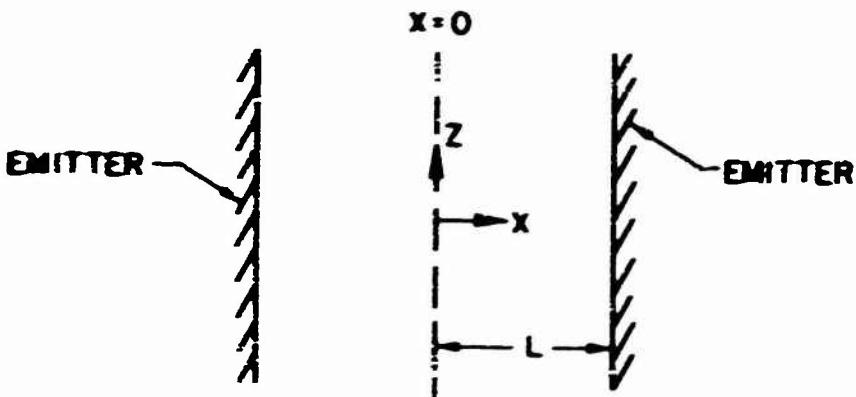

FIG. 2.1. EMITTER GEOMETRY

In the past a great deal of work has been done on diodes consisting of thermionic emitters. The majority of these papers deal with the study of dc and oscillating states with a nonzero dc potential applied across the diode. An early work on the thermionic diode with zero net potential was given by Nottingham,¹ who treated the problem in the absence of ions. Without the ions he found that the electron density was highly nonuniform, even if the spacing was much greater than the Debye length, the density at the midplane was very low. Eichenbaum and Hernqvist²⁵ included the ion emission but studied the problem using the collisionless Boltzmann equation, never allowing the empty regions of the phase space to fill up. Figure 2.2 illustrates the model used by Eichenbaum and Hernqvist with the shaded region of the ion phase space unfilled. Such a nonequilibrium analysis is not realistic when there is no net potential across the diode. Langmuir²⁶ examined an equilibrium case but with one of the planes at infinity.

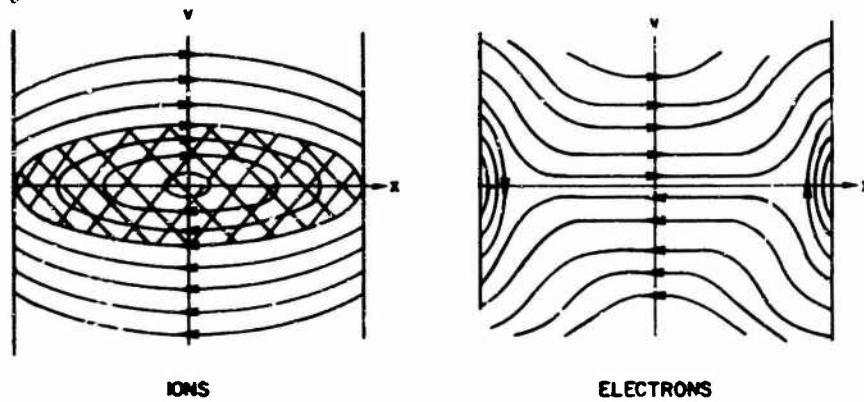

FIG. 2.2. PHASE SPACE SKETCH FOR THE ELECTRONS AND IONS.

In our problem, we assume a strict thermodynamic equilibrium and fill the phase space completely according to Boltzmann's probability law, and hence the scale-height law is used for the electron and ion densities. By taking the potential to be zero at the midplane ($x = 0$), Poisson's equation becomes

$$\begin{aligned} \frac{d^2V}{dx^2} &= -\frac{e}{\epsilon_0} [n_+(x) - n_-(x)] \\ &= -\frac{e}{\epsilon_0} \left\{ n_+(0) \exp\left[-\frac{eV}{kT}\right] - n_-(0) \exp\left[\frac{eV}{kT}\right] \right\}. \end{aligned} \quad (2.1)$$

At this point normalized quantities

$$\xi = \frac{x}{\sqrt{2} \lambda_{D0}} ,$$

$$\eta = \frac{eV}{\kappa^m}$$

and

$$\alpha^2 = \frac{n_+(0)}{n_-(0)}$$

with the Debye length at $x = 0$,

$$\lambda_{D0} = \left(\frac{\epsilon_0 \kappa T}{n_-(0) e^2} \right)^{1/2} ,$$

are introduced, and Eq. (2.1) is thus reduced to

$$\frac{d^2 \eta}{d\xi^2} = 2[e^\eta - \alpha^2 e^{-\eta}] . \quad (2.2)$$

Let us first consider the case of $\alpha < 1$, the "electron" rich case.

The boundary condition at $\xi = 0$ is

$$\eta = 0 , \quad \eta' = 0 .$$

By introducing a new variable

$$w^2 = e^\eta , \quad (2.3)$$

the solution to Eq. (2.2) is found to be

$$F(\alpha, w) = K(\alpha) - \xi \quad (2.4)$$

where $F(\alpha, w)$ is the elliptic integral of the first kind²⁷ with modulus α ,

$$F(\alpha, \nu) = \int_0^{\nu} \frac{dt}{\sqrt{(1-t^2)(1-\alpha^2 t^2)}} \quad (2.5)$$

and $K(\alpha) = F(\alpha, 1)$ is the complete elliptic integral. Tables for these integrals are available.

By inverting Eq. (2.4), we obtain

$$\nu = \operatorname{sn}[K(\alpha) - \xi, \alpha] \quad (2.6)$$

where $\operatorname{sn}[K(\alpha) - \xi, \alpha]$ is the Jacobi elliptic function with modulus α and argument $K(\alpha) - \xi$. Hence,

$$\tau = -2 \ln \operatorname{sn}[K(\alpha) - \xi, \alpha]. \quad (2.7)$$

Equation (2.7) enables us to calculate the potential as a function of z provided α is known. Generally, α is a quantity we seek in terms of a similar quantity given at the emitter surface. Let

$$z^2 = \frac{n_+(L)}{n_-(L)}.$$

We know from the scale-height law that

$$n_-(L) = n_-(1) \exp(-\tau_L)$$

and

$$n_+(L) = n_+(1) \exp(-\tau_L).$$

Hence,

$$\frac{n_+(L)}{n_-(L)} = \frac{n_+(1)}{n_-(1)} \exp(-2\tau_L).$$

or

$$z^2 = \alpha^2 e^{-2\tau_L}.$$

The subscript L denotes quantities evaluated at the surface of the emitter. Since

$$\xi = \frac{x}{\sqrt{2} \epsilon_{DL}} = \frac{x}{\sqrt{2} \epsilon_{DL}} \frac{\epsilon_{DL}}{\epsilon_D} = -\frac{x}{\sqrt{2} \epsilon_{DL}} \left(\frac{\epsilon_D(z)}{\epsilon_D(L)} \right)^{1/2} = \frac{x}{\sqrt{2} \epsilon_{DL}} \exp \left(-\frac{z}{L} \right) = \frac{x}{\sqrt{2} \epsilon_{DL}} v_L,$$

Eq. (2.4) can be rewritten as

$$\frac{x}{\sqrt{2} \epsilon_{DL}} = \frac{E(z) - F(z, v_L)}{v_L}. \quad (2.5)$$

We evaluate Eq. (2.5) at $x = L$ and obtain

$$\frac{L}{\sqrt{2} \epsilon_{DL}} = \frac{E(z) - F(z, v_L)}{v_L}. \quad (2.6)$$

With Eq. (2.6) a family of curves, L/ϵ_{DL} versus β with β as a parameter, can be plotted as shown in Fig. 2.3. From the graph β can be determined for given values of L and $L/\sqrt{2} \epsilon_{DL}$, and, consequently, v_L , $\epsilon_D(z)$ and $\epsilon_D(L)$ can be obtained.

The following properties of the Jacobi elliptic function and the elliptic integrals are worth noting here.²⁴ For $\beta = 1$ we have

$$\sin z, z \approx \sin z - \frac{z^2}{2} \cos z (z - \sin z \cos z) \dots \quad (2.10)$$

$$E(z) \approx \frac{1}{2} + z^2 \frac{1}{2} \dots \quad (2.11)$$

Thus, for $\beta = 1$, Eq. (2.6) becomes

$$- \approx -2 dz \left[\sin \left(\frac{z}{2} - \frac{1}{2} \right) \right]$$

which is the relation obtained by Rutherford for the case of a bare electron cloud.

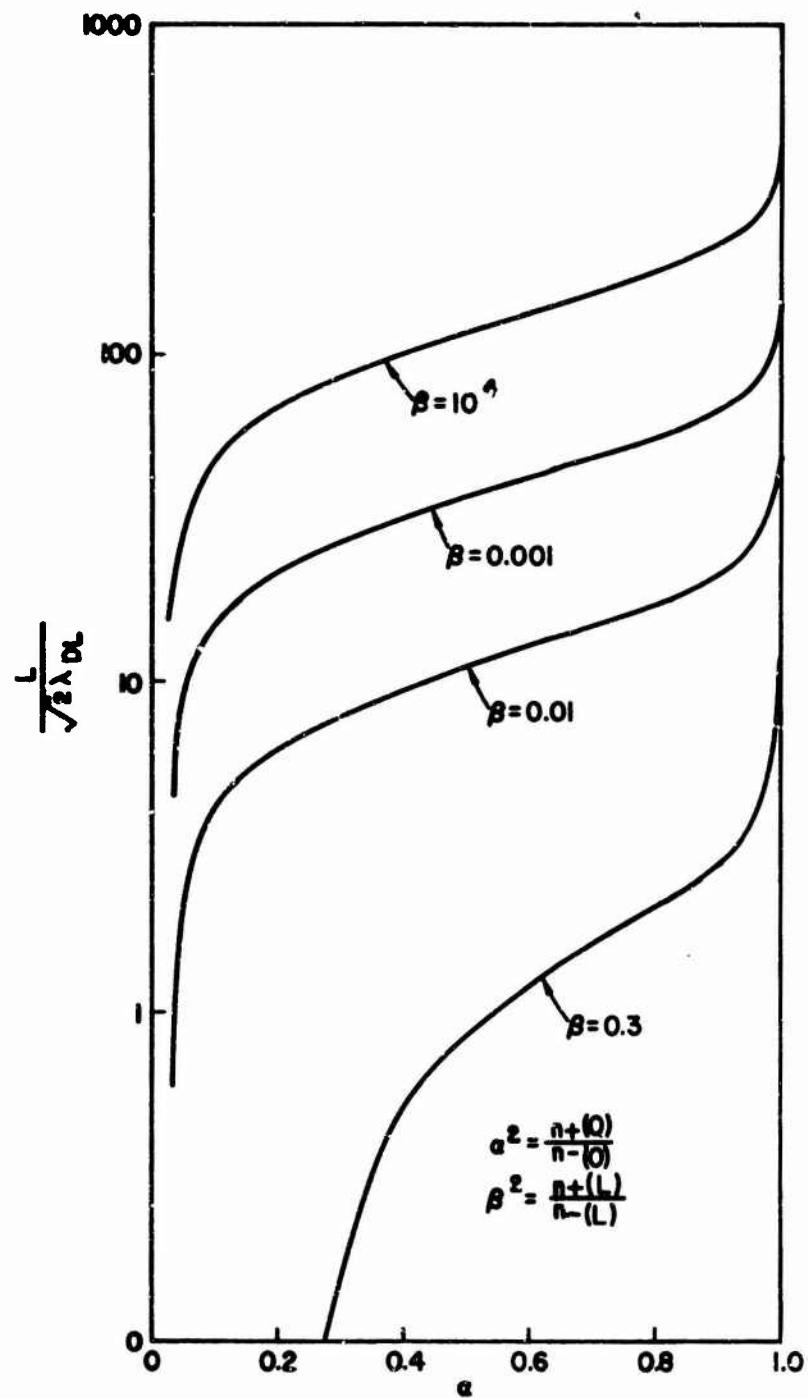

FIG. 2.3. RATIO OF ELECTRON AND ION DENSITY,
 $\alpha^2 = n_+(0)/n_-(0)$, IN MID-PLANE AS A FUNCTION OF
 SEPARATION DISTANCE $2L$ IN UNITS OF DEBYE LENGTH
 λ_L FOR DIFFERENT VALUES OF $\beta^2 = n_+(L)/n_-(L)$.

For α approaching unity we have

$$sn(u, \alpha) \approx \tanh u + \frac{1}{4} (1-\alpha^2) \operatorname{sech}^2 u [\sinh u \cosh u - u] \dots \quad (2.12)$$

and

$$K(\alpha) \approx \ln \left[\frac{4}{(1-\alpha)^{1/2}} \right] \dots \quad (2.13)$$

For small values of w or $\sqrt{\beta/\alpha}$, we also have

$$F(\alpha, w) \approx w - \frac{1}{6} w^2 (1+\alpha^2) \dots \quad (2.14)$$

By shifting the origin to the wall,

$$\xi' = -\xi + L ,$$

using Eq. (2.9) and letting the other wall go to infinity ($\alpha \rightarrow 1$), we obtain from Eq. (2.7)

$$\begin{aligned} \eta &\approx -2 \ln [F(1, \sqrt{\beta}) + \xi', 1] \\ &\approx -2 \ln [\sqrt{\beta} + \xi', 1] \\ &\approx -2 \ln [\tanh (\sqrt{\beta} + \xi')] \end{aligned} \quad (2.15)$$

which is the result given by Langmuir for the semi-infinite plasma bounded by an emitting plane.

Thus far, we have been concerned with electron rich cases. The ion rich cases can be derived simply by re-defining the parameters α , β , η and λ_{D0}^2 as shown in the table below.

<u>Symbol</u>	<u>Electron Rich</u>	<u>Ion Rich</u>
β^2	$n_+(L)/n_-(L)$	$n_-(L)/n_+(L)$
α^2	$n_+(0)/n_-(0)$	$n_-(0)/n_+(0)$
λ_{D0}^2	$\kappa T \epsilon_0 / (e^2 n_-(0))$	$\kappa T \epsilon_c / (e^2 n_+(0))$
η	$eV/\kappa T$	$-eV/\kappa T$

With the new definitions, the Poisson's equation becomes identical to Eq. (2.2) with $\alpha \leq 1$.

B. NUMERICAL EXAMPLES WITH PURE METAL EMITTERS

To give some idea of the types of densities and potential profiles which can be expected inside a "black body," we give some numerical results based on emission data of pure refractory metals. In practice the quantity $\beta^2 = n_+(L)/n_-(L)$ is not easily obtained because the data on ion emission rate from various metals are scarce. For the numerical computations we use the following empirical formula on ion emission from molybdenum emitter as given by Wright²⁹ and the Richardson equation for electron emission. Current densities are given in amps per cm^2 .

$$\ln J_+ = 28.39 - \frac{e\phi_+}{kT} - 0.453 \ln T + 6.22 \times 10^{-4} T, \quad (2.16a)$$

$$J_- = AT^2 \exp\left(-\frac{e\phi_-}{kT}\right) \quad (2.16b)$$

with

$$A = 55 \text{ amp/cm}^2$$

$$\phi_+ = 8.3 \text{ volts}$$

$$\phi_- = 4.37 \text{ volts}.$$

In the computation the emitters are assumed to be 1 cm apart. In Fig. 2.4 plots of n_o , $n_+(0)$, $n_-(0)$ and λ_{D0} versus $1/T$ are given. The neutral density n_o is obtained from the data provided by Honig.³⁰ The graphs show that above 2000°K the space charge is practically neutralized at $x = 0$. For $T < 1800^\circ\text{K}$ the diode space consists almost entirely of electrons, the density is very low and the Debye length is of the order of the diode separation. Figs. 2.5 and 2.6 give potential and density profiles for $T = 2200^\circ\text{K}$.

We were somewhat startled to find that the space charge neutralization requires only a small amount of ion emission from the walls. For the example shown in Fig. 2.6, the ion density at the wall is $10^6/\text{cc}$, which

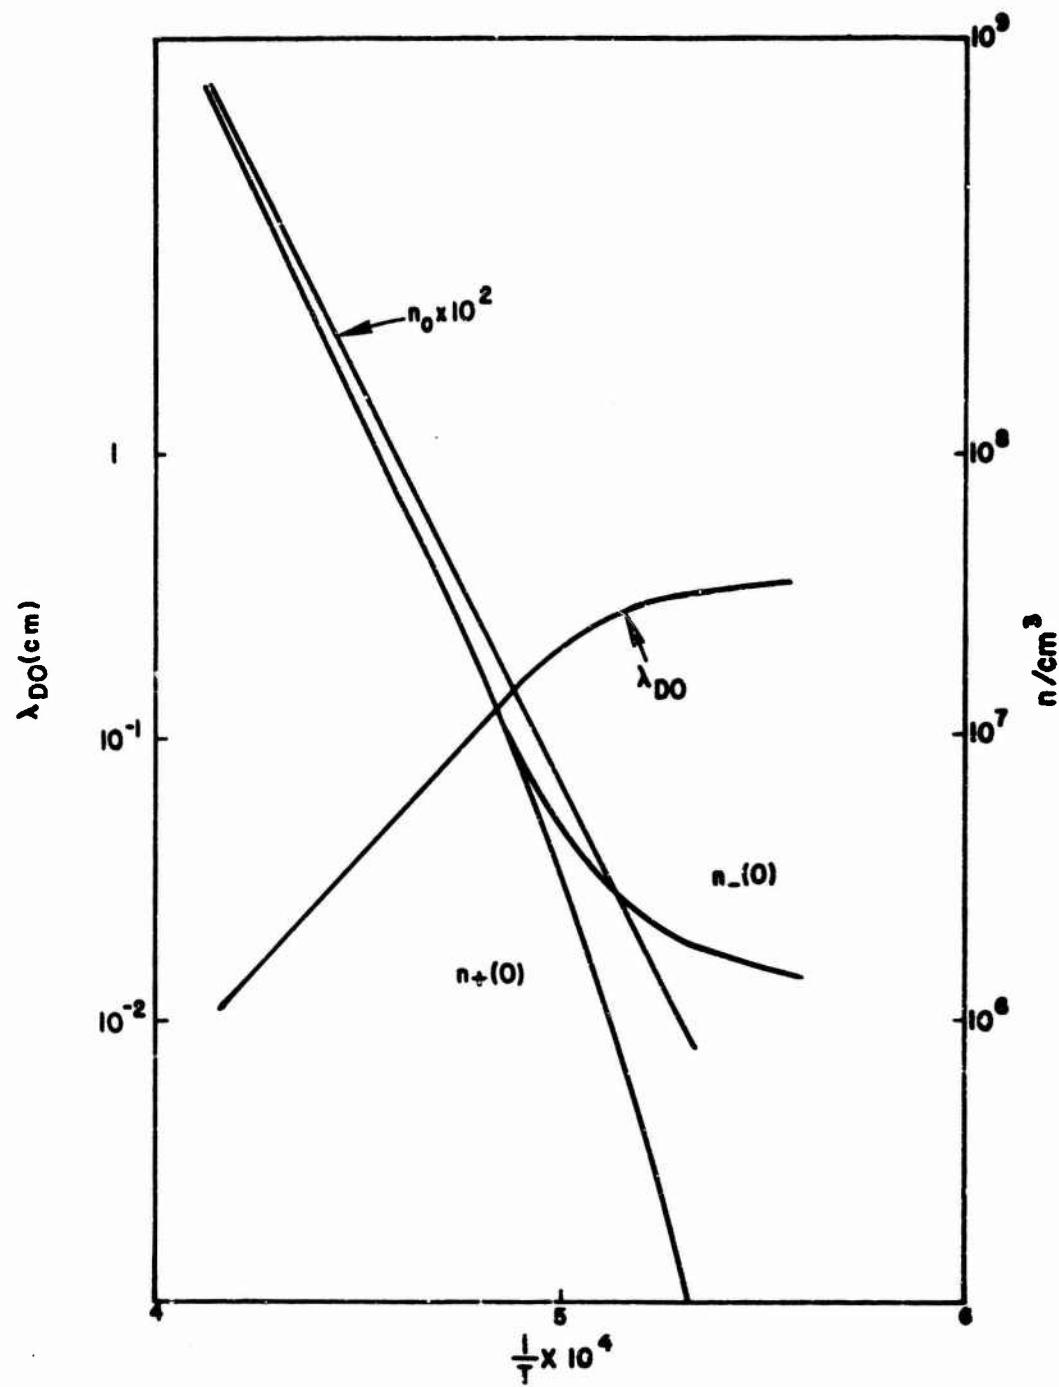

FIG. 2.4. ELECTRON DENSITY, $n_-(0)$, ION DENSITY, $n_+(0)$, DEBYE LENGTH λ_{D0} IN MID-PLANE, AND THE NEUTRAL DENSITY n_0 AS A FUNCTION OF $1/T$ FOR A PURE MOLOPDENUM EMITTER.

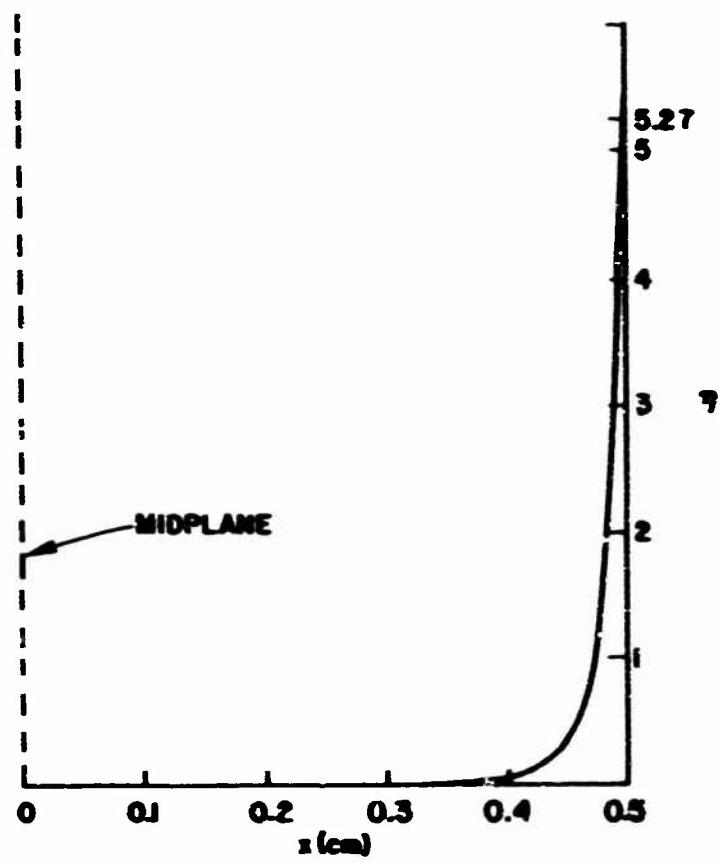

FIG. 2.5. ELECTROSTATIC POTENTIAL $\eta = eV/kT$ AS A FUNCTION OF THE DISTANCE FROM MID-PLANE.

corresponds to an ion current density of 10^{-9} amps/cm². Even with such a small ion emission rate, we can derive a neutral plasma whose density is orders of magnitude greater than that predicted by the analysis of Nottingham (ions absent) or Eichenbaum and Hernqvist (nonequilibrium analysis with unfilled regions in phase space).

The midplane electron density, ion density and neutral density versus $1/T$ for tungsten and niobium are shown in Figs. 2.7 and 2.8. For tungsten the data on the neutral density are obtained from graphs provided by Honig, and the following empirical formula as given by Smith³¹ is used to compute the ion density at the tungsten emitter.

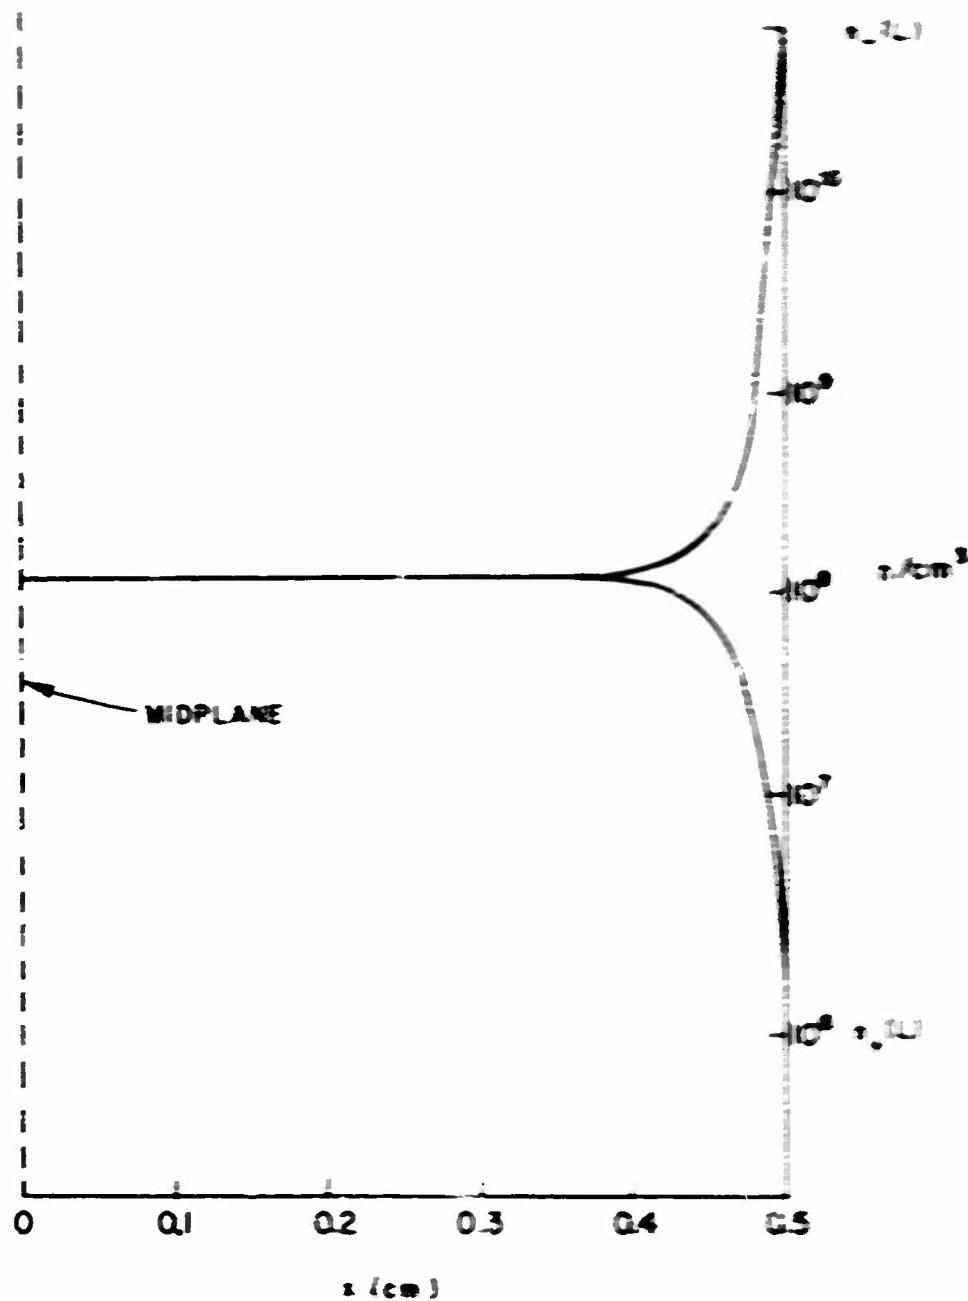

FIG. 2.6. ELECTRON DENSITY n_e AND ION DENSITY n_i AS FUNCTIONS OF THE DISTANCE FROM THE MID-PLANE.

$$\ln \frac{I_0}{I_s} = 0.369 \ln \frac{V}{V_s} + 1.62 \cdot 10^{-7} \cdot \frac{V^2}{V_s^2} + -\frac{V^2}{2.35 \cdot 10^{-7}} + 12.43 \quad (2.17)$$

and $V_s = 11.9$ volts. The result for tungsten emitters is qualitatively similar to that of the molybdenum emitter. The calculation for the molybdenum emitter is based on the test emission data obtained in the laboratory by the author.³² The molybdenum emission data obeyed the following empirical relation:

$$\ln \frac{I_0}{I_s} = 2.01 - \frac{V^2}{V_s^2} - 1.55 \ln \frac{V}{V_s} - 2.4 \cdot 10^{-7}$$

and $V_s = 11.9$ volts. The current densities are given in amp per cm^2 . The current density for emission is obtained from vapor pressure data generated by Ramanathan.³³

C. EMISSION REGION IN THE BESSEL CLASSICAL Emitter

We now consider the cylindrical emitter, as shown in Fig. 2.5, to see the effect of the geometry on the plasma density and the sheet potential. Under the condition

$$\frac{r}{R} \cdot \frac{z}{R} \ll 1$$

Pearson's equation is given as

$$\frac{\partial^2}{dz^2} \cdot \frac{1}{z} \frac{\partial}{\partial z} \psi - \frac{e}{k} \left[n_e(z) - n_i(z) \right] \quad (2.18)$$

Again the scale-height law is assumed to govern the density distribution, and hence,

$$\frac{\partial^2}{dz^2} \cdot \frac{1}{z} \frac{\partial}{\partial z} \psi - \frac{e}{k} \left\{ n_e(1) - \left(\frac{1}{z} \right) \cdot n_e \left(1 - \frac{z}{R} \right) \right\} - \frac{e}{k} \left\{ n_i(1) - \left(\frac{1}{z} \right) \cdot n_i \left(1 - \frac{z}{R} \right) \right\} \quad (2.19)$$

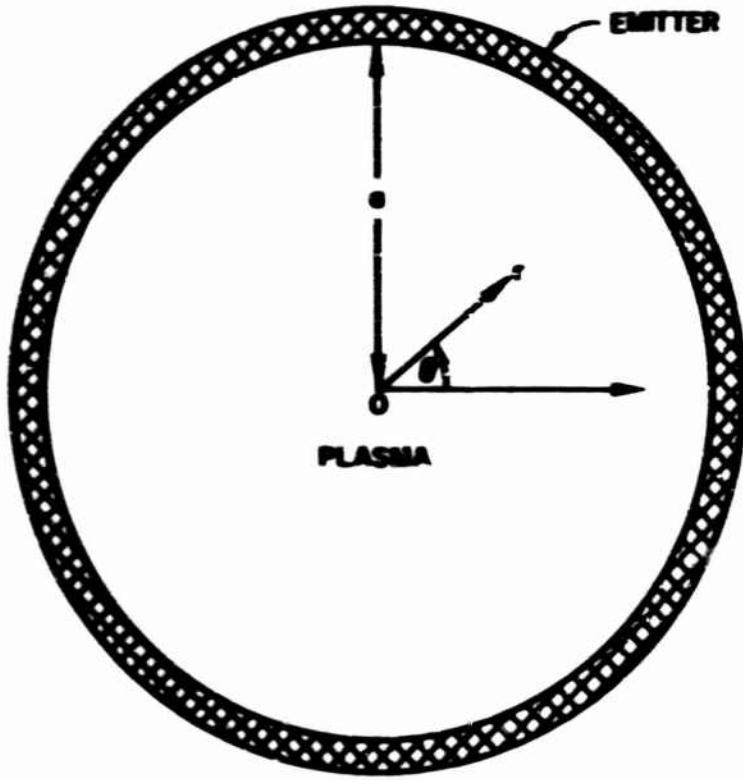

FIG. 2.9. CYLINDRICAL EMITTER OF RADIUS a .

where $n_i(0)$ and $n_e(0)$ are the ion and electron densities at $r = 0$. Normalization similar to those of Section A yields

$$\frac{d^2 n}{dr^2} + \frac{1}{r} \frac{dn}{dr} = e^2 - a^2 e^{-r/a} \quad (2.20)$$

where

$$e = \frac{r}{\lambda_D} = r \sqrt{\frac{e^2 n_e(0)}{4\pi \epsilon_0 c}}.$$

Equation (2.20) cannot be solved in terms of classical transcendental equations. An analytic solution does exist, however, when the ions are absent ($a = 0$). For this special case the solution is given by

$$n = n_e \ln \left(1 - \frac{r^2}{a^2} \right). \quad (2.21)$$

For the general case of nonzero α , one must resort to numerical integration. The following normalization is found to be convenient for numerical analysis

$$\rho' = \sqrt{\alpha} \rho = \frac{r}{\lambda_{DC}} \sqrt{\alpha} = \frac{r}{\lambda_s} \sqrt{\beta}, \quad \lambda_s = \sqrt{\frac{\kappa T \epsilon_0}{e^2 n_e(s)}}$$

The variable ρ' measures the radius in units of $\lambda_s/\sqrt{\beta}$, which is a known quantity, while the variable ρ is normalized to λ_{DC} , which is not known a priori. Poisson's equation now becomes

$$\frac{d^2\eta}{dp'^2} + \frac{1}{\rho'} \frac{d\eta}{dp'} = \frac{1}{\alpha} [e^\eta - \alpha^2 e^{-\eta}] \quad (2.22)$$

or by re-arranging the right hand side we have

$$\frac{1}{\rho'} \frac{d}{dp'} \left(\rho' \frac{d\eta}{dp'} \right) = \frac{1}{\alpha} [\epsilon \sinh \eta + \delta^2 e^{-\eta}] \quad (2.23)$$

where

$$\delta^2 = 1 - \alpha^2$$

Equation (2.23) introduces a parameter δ^2 which is generally a small number directly proportional to the fractional deviation from neutrality at $\rho' = 0$. For computational purposes, we used Eq. (2.23). For a given value of α , a series solution can be obtained for small values of ρ' . Let

$$\eta = a_1 \rho' + a_2 \rho'^2 + a_3 \rho'^3 + a_4 \rho'^4 \dots$$

Then

$$\frac{1}{\rho'} \frac{d}{dp'} \left(\rho' \frac{d\eta}{dp'} \right) = \frac{a_1}{\rho'} + 2a_2 + 6a_3 \rho' + 10a_4 \rho'^2 \dots$$

$$\sinh \eta = a_1 z^1 + a_2 z^{1^2} + \left(a_3 + \frac{1}{2} a_1^3 \right) z^{1^3} \dots$$

and

$$e^{-\eta} = 1 - a_1 z^1 + \left(\frac{a_1^2}{2} - a_2^2 \right) z^{1^2} + \left(a_1 a_2 - a_3 - \frac{1}{2} a_1^3 \right) z^{1^3} \dots$$

By inserting these relations into Eq. (2.23) and equating the coefficients of the like power terms, we get

$$a_{2n+1} = 0 \quad \text{for } n = 0, 1, 2, 3, \dots$$

$$a_2 = \frac{z^2}{48}$$

$$a_4 = \frac{1}{192} (2 - z^2) a_2$$

$$a_6 = \frac{1}{3840} \left[(2 - z^2) a_4 + \frac{z^2 a_2^2}{2} \right]$$

$$a_8 = \frac{1}{960} \left[(2 - z^2) a_6 + \frac{a_2^3}{3} - \frac{z^2 a_2^2}{2} + z^2 a_2 a_4 \right]$$

Using this solution as the starting point, the differential equation is integrated numerically by a SUBRoutines procedure called "Adams Predictor-Corrector Method," available at the Stanford Computation Center. The integration procedure is repeated with different values of β until the boundary condition at the wall is satisfied. The resulting potential profiles for a polyacetylene emitter are shown with the temperature as a parameter in Fig. 2.11. The diameter of the emitters is taken to be 1 cm. The curves show that the density and potential profiles for the cylindrical system look like those of the planar system when the radius is much larger than the Debye length, l_D .

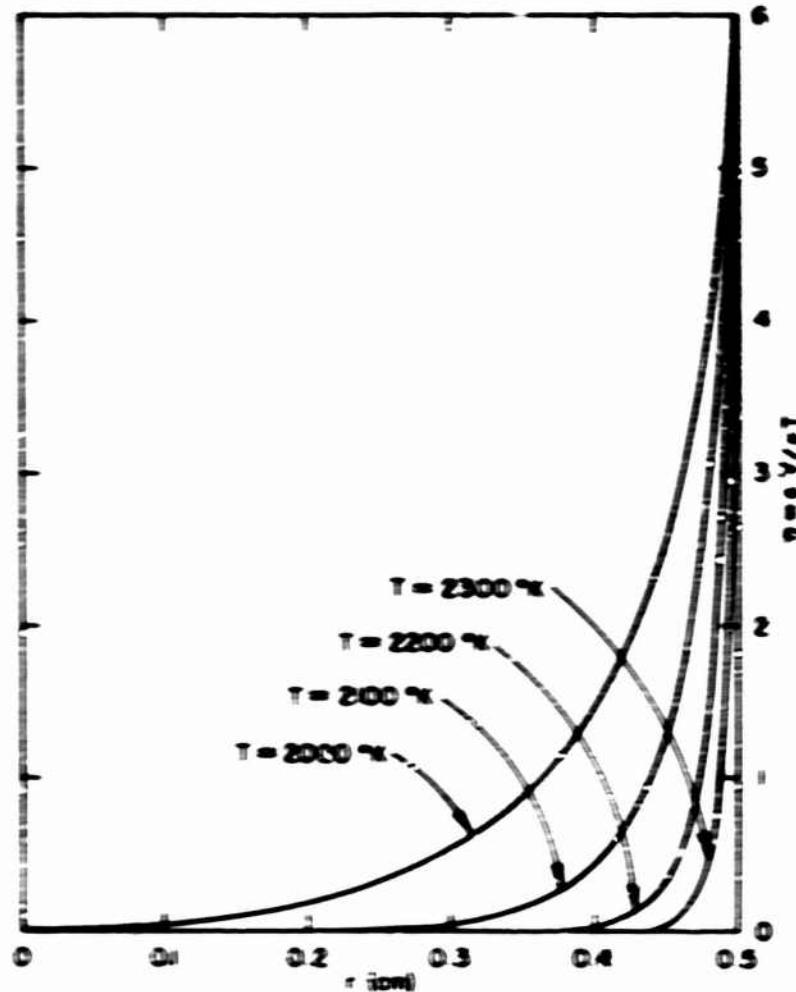

FIG. 2.10. POTENTIAL PROFILE INSIDE A HOLLOW CYLINDRICAL HELIUM GUN BITTER FOR DIFFERENT TEMPERATURES.

3. CONDUCTIVE IONIZATION PLASMAS

In 1923 Langmuir and Ingold²⁴ showed that, when a neutral atom strikes a hot metal whose work function is greater than the ionization potential of the atom, the atom bounces off the metal as an ion with high probability. Since Langmuir's demonstration many papers have been written on this subject, and, in fact, many of the plasma generators designed today are based on this phenomena. An excellent theoretical treatment of the surface phenomena involved with the so-called contact ionization process is given in a recent series of papers by Levine and Cyftopoulos.^{25,26,27} They derive the emission rates of the ions, electrons and atoms under thermodynamic equilibrium conditions. The emission rates ν_i , ν_e and ν_a are given in terms of temperature and the

fraction δ of the metal surface covered by a mono-layer of adsorbent. Under steady state conditions, ion and atom emission rates are equated to the arrival rates of the ions and atoms μ_i and μ_a .

$$Y_a + Y_i = \mu_a + \mu_i$$

To obtain the steady state coverage, we assume $Y_i = \mu_i$, and the atom emission rate is equated to the atom arrival rate which is computed from the vapor pressure of the adsorbent material. In this manner, the steady state coverage δ is determined and hence emission rates can be computed. Strictly speaking, our computations violate the thermodynamic equilibrium condition since we assume that the vapor temperature is not necessarily equal to the metal temperature. Using the resulting emission data, we compute the density and potential profiles for several different sets of conditions. Shown in Figs. 2.11 and 2.12 are the profiles for a typical case with cesium vapor and tungsten emitters. Note that the space charge is neutral in the greater portion of the diode space despite the large difference in the electron and ion densities at the wall.

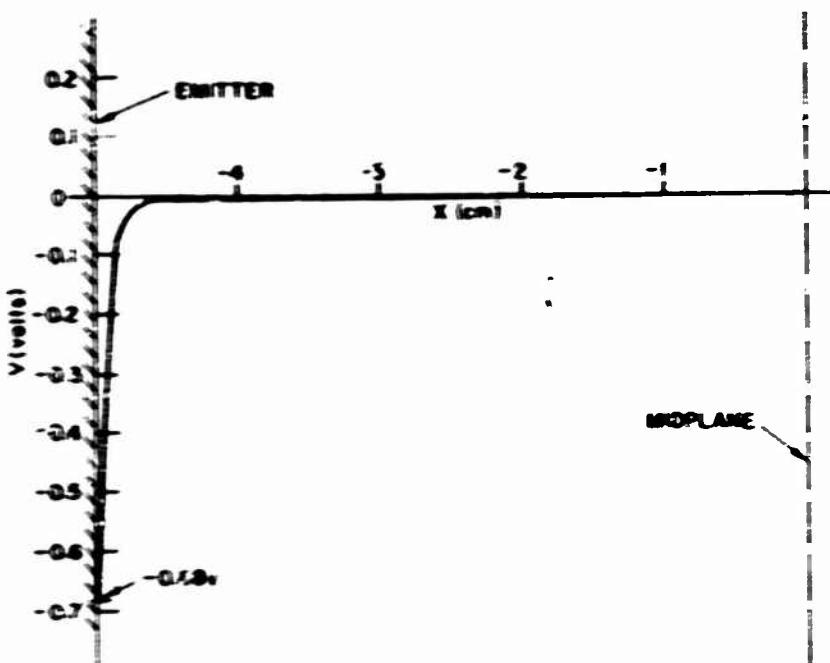

FIG. 2.11. THEORETICAL DC POTENTIAL PROFILE FOR A DIODE WITH TUNGSTEN WALLS AND CESIUM VAPOR. For the computation, the wall temperature was 1301 °K and the vapor temperature was 31 °C. The wall separation was taken to be 1 cm.

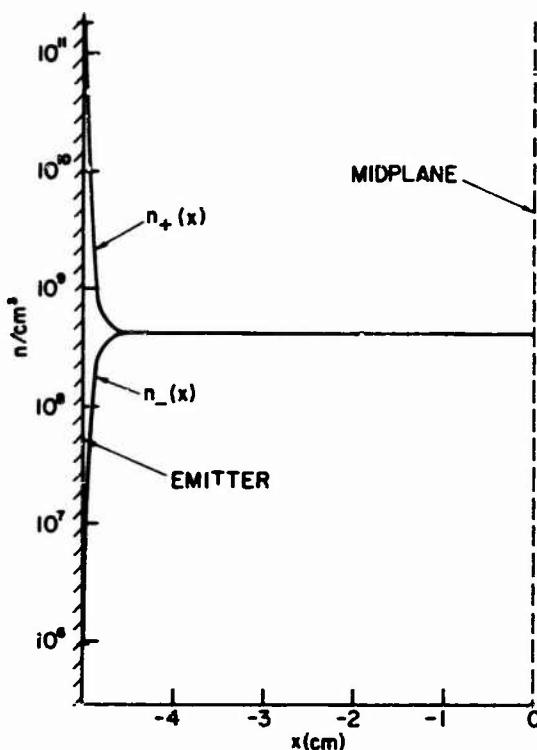

FIG. 2.12. ION AND ELECTRON DENSITY PROFILE. The conditions are identical to those of Fig. 2.11.

The midplane densities for sufficiently large plate separation ($L \gg \lambda_{D0}$) are computed for tantalum emitters with sodium, potassium and cesium vapors. Shown in Figs. 2.13, 2.14 and 2.15 are the midplane plasma frequency and the Debye lengths as functions of emitter temperature with the vapor temperature as a parameter. In the range of emitter temperatures covered, the Ta-Na system is electron rich, the Ta-K system is either electron or ion rich depending on the emitter temperature, and the Ta-Cs system is ion rich. It is interesting to note that even with sodium, whose ionization potential is higher than the work function of tantalum, a good workable plasma can be obtained. The probability of a sodium atom being ionized by tantalum is small, but a sufficiently high number become ionized to neutralize the electron space charge in the diode space.

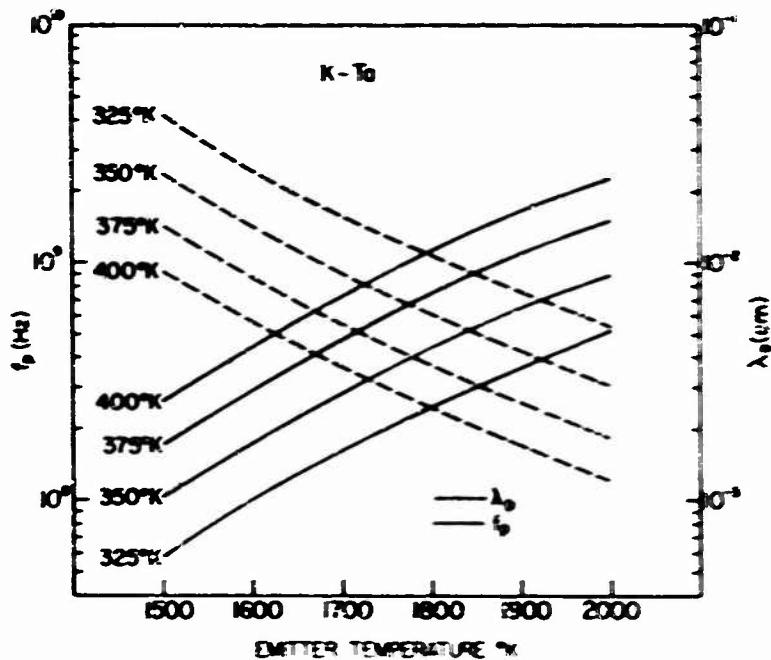

FIG. 2.14. PLASMA FREQUENCY AND THE DEBYE LENGTH FOR A POTASSIUM PLASMA PRODUCED BETWEEN TWO TANTALUM PLATES. The quantities are plotted as functions of tantalum temperature with potassium vapor temperature as a parameter.

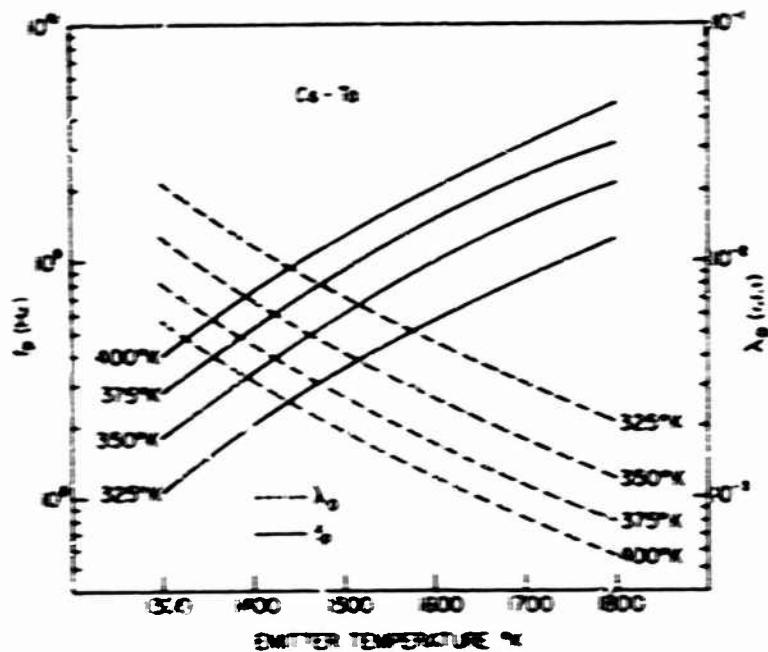

FIG. 2.15. PLASMA FREQUENCY AND THE DEBYE LENGTH FOR A CESIUM PLASMA PRODUCED BETWEEN TWO TANTALUM PLATES. The quantities are given as functions of test-tube temperature with cesium vapor temperature as a parameter.

I. DENSITY MEASUREMENTS WITH SODIUM PLASMA

Sodium plasma is produced in a diode which is described in the schematic drawings of Figs. 2.16 and 2.17. The diode consists of two circular tantalum buttons of diameter 1.6 inches separated by 1 inch. The buttons are heated by electron bombardment, and the whole tube is immersed in an oil bath to keep the tube temperature uniform and low. Provision is made also to vary the oil bath temperature. The two gridded probes are for the Langmuir wave measurements discussed elsewhere.³² The density is measured by a Langmuir probe consisting of a long wire of 15/1000 inch diameter. The probe is provided with an accurate meter which indicates the probe distance from the center line, and provisions are made to permit angular motion of the probes as well. The buttons are surrounded by heat shields which also act as guard rings. To confine the plasma in the radial direction and make the diode closely approximate an infinite system, an axial magnetic field is applied.

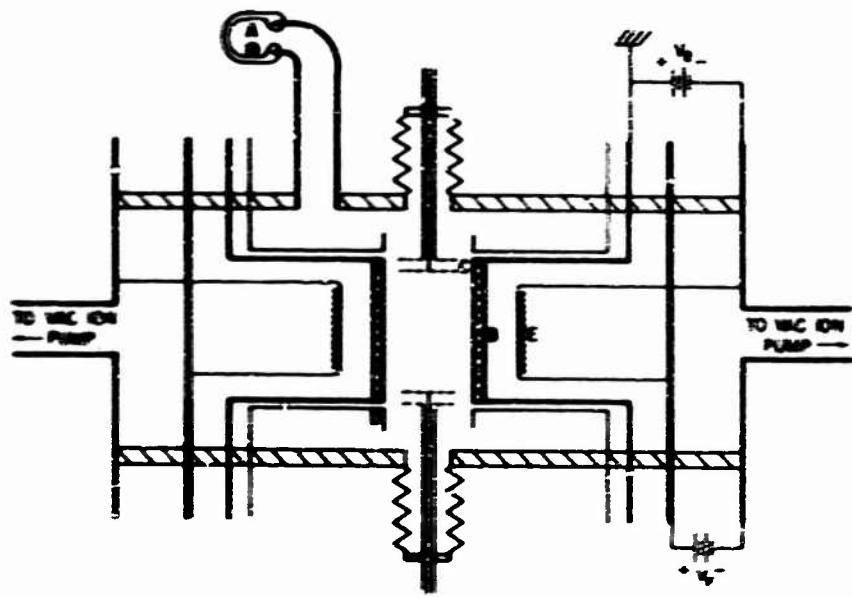

FIG. 2.16. SCHEMATIC DRAWING OF THE PLASMA TUBE. A = sodium vapor source; B = tantalum plates; C = gridded probe; D = heat shield (guard ring); E = bombarder filament; V_B = bombarder power supply; V_f = filament power supply.

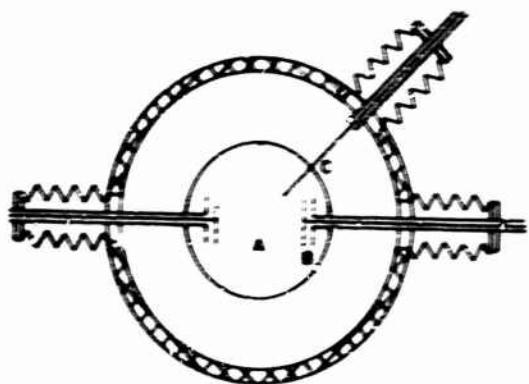

FIG. 2.17. SCHEMATIC DRAWING OF THE PROBE SYSTEM. A = tantalum plate; B = gridded probe; C = Langmuir probe.

The plasma density is found to be highly dependent on the guard-ring potential, as was noted also by Omlor.³⁹ The curves of Fig. 2.14 show the probe characteristics for various guard-ring potentials with a magnetic field of 350 gauss applied. Shown in Fig. 2.15 are the experimental and theoretical plasma frequencies as fractions of the button temperature. The data are taken with the probe tip 2 mm from the center line, the guard ring biased positive and an axial magnetic field of 350 gauss applied. In the analysis of the data, we take that portion of the probe which is inside the cathode radius to compute the effective area of the probe. Hence, this method gives only the average density of the plasma. Nevertheless, the agreement between the theory and the experiment is good.

With the oil bath temperature at 325°K, the neutral sodium density computed from vapor pressure data is 3×10^{11} /cc. The plasma density with the button temperature at 2111°K is 2×10^{11} /cc, which represents 46 percent ionization. Higher percentage ionization can be achieved at higher button temperatures. When a hard sphere model is used for sodium atoms, the electron-neutral collision frequency is about 3 Hz, while the plasma frequency is about 3 MHz for the conditions above.

From the measurements we can conclude that the sodium plasma is不适 suited for low density quiescent plasma experiments. Undesirable effects, such as disappearance of the vapor source, shorting of the electrodes due to sodium coating and corrosion, are not noticeable. We believe that this is the first sodium plasma produced by the resonance ionization process. On the basis of our conclusions, Berlier and Simonet³⁷ decided to use the Na-Ta system in their London damping experiment.

Because α and β have the advantage of being the sum of the previous
degree to derive the α values of the class.

$$\frac{d^2}{dt^2} \left(\frac{1}{t} + \frac{1}{t^2} - \frac{1}{t^3} + \frac{1}{t^4} - \frac{1}{t^5} + \dots \right) = \frac{1}{t^3} - \frac{2}{t^4} + \frac{3}{t^5} - \dots$$

$$= \frac{1}{t^3} + \frac{1}{t^4} + \frac{1}{t^5} + \dots + \left(-\frac{1}{t^3} + \frac{2}{t^4} - \frac{3}{t^5} + \dots \right)$$

where $\frac{d^2}{dt^2} \left(\frac{1}{t} + \frac{1}{t^2} - \frac{1}{t^3} + \frac{1}{t^4} - \frac{1}{t^5} + \dots \right)$ is the sum of the first two terms of the expansion of $\frac{1}{t} e^{-t}$. Notice that all of the remaining terms cancel out and the expansion reduces to the first term in the expansion of e^{-t} .

$$= \frac{1}{t^3} + \frac{1}{t^4} + \frac{1}{t^5} + \dots + \left(-\frac{1}{t^3} + \frac{2}{t^4} - \frac{3}{t^5} + \dots \right)$$

and the n -th term is the sum of the first n terms from $t = 1$. Our method can't give a representation of e^{-t} but we still have the information in the expansion of e^{-t} . The terms of e^{-t} are now known up to the n -th term.

1.1.1. Boundary Conditions

Boundary conditions are trivial and we will use the condition sufficient to force the terms a_{n+1}, a_{n+2}, \dots of the series $\sum a_n t^n$ to be zero. This is equivalent to specifying derivatives. By taking initial derivatives of e^{-t} at the value $t = 0$ we obtain the boundary conditions. The boundary conditions for the boundary conditions of e^{-t} are $a_0 = 1$, $a_1 = -1$, $a_2 = 2$, $a_3 = -3$, $a_4 = 4$, $a_5 = -5$, $a_6 = 6$, $a_7 = -7$, $a_8 = 8$, $a_9 = -9$, $a_{10} = 10$, and so on. Since we are looking for a power series, all the coefficients a_n must be real numbers. However, we hope to get some insight into the behavior of complex series please ignore.

1.1.2. Error Term

By using the following expansion and definition

Note that $\frac{1}{t}$ is the dominant term in

$$L_1 = \frac{d}{dx} + \frac{d^2}{dx^2}$$

λ = known eigenvalues of L_1

$$\frac{1}{\lambda - L_1}$$

$$\frac{1}{\lambda - L_2}$$

and $\frac{1}{\lambda - L_3}$ = known eigenvalues of L_3

$$\frac{1}{\lambda - L_1} + \frac{1}{\lambda - L_2} + \frac{1}{\lambda - L_3} = \frac{1}{\lambda - L}$$

The use of boundary conditions will now be explained. In Chapter 10 Boundary Value Problems involving second order linear differential equations we discussed the boundary conditions of the two-point boundary value problem and how different conditions could appear at the endpoints. Now Chapter 10 states the basic where the boundary conditions are simpler than those in boundary value problems involving second order linear differential equations. One of the most basic boundary conditions is the homogeneous boundary condition. This condition states that the function y and its derivative y' are zero at the left endpoint. This means that the function y is zero at the left endpoint and the derivative of y is zero at the left endpoint. The boundary condition at the right endpoint is the same as the left endpoint. The homogeneous boundary condition is also called a homogeneous boundary condition. It is called a homogeneous boundary condition because it does not involve any coefficients. The boundary condition at the left endpoint is approximately zero at the left endpoint. The boundary condition at the right endpoint is approximately zero at the right endpoint. These terms are the two boundary conditions of the differential equation. They are the two boundary conditions of the differential equation.

Homogeneous boundary conditions

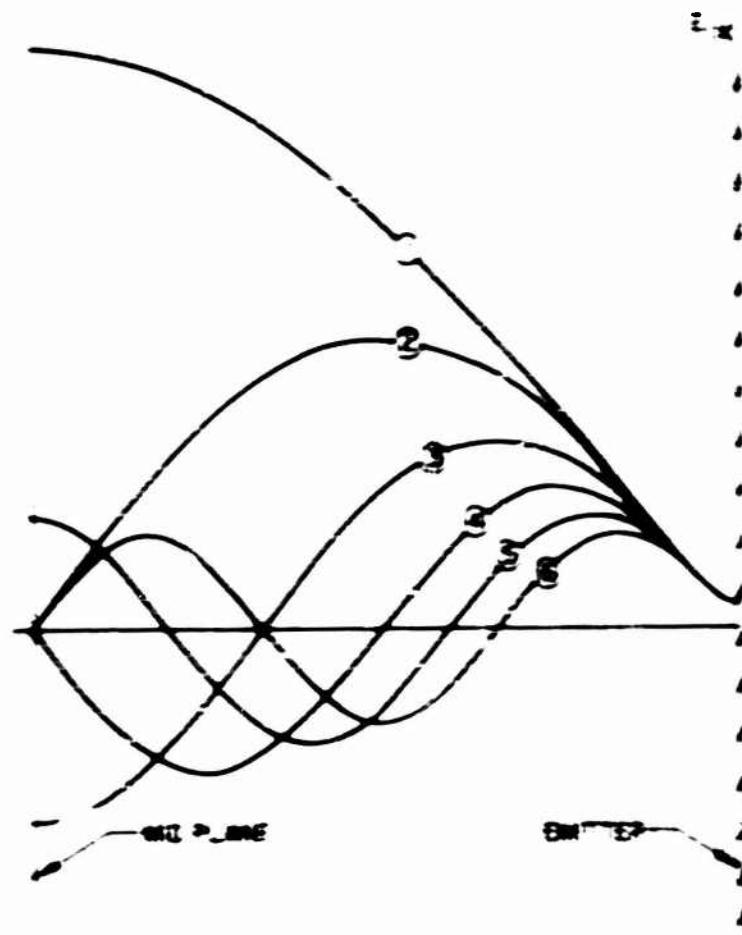

FIG. 1. - EMISSION AND PROPAGATION OF THE FIRST TWO RESONANCES FOR AN OSCILLATING SOURCE LOCATED IN OIL AT $T = 20^\circ\text{C}$. The modes are numbered and the corresponding frequencies in cps given in Table I.

$$\frac{\omega}{\omega_0} = \frac{1 + \frac{2\pi c}{\lambda}}{1 + \frac{2\pi c}{\lambda_0}}$$

where λ is the wavelength and n the wave number. As resonance we get $\omega = \omega_0$ where $\lambda = \lambda_0$ (labeled) and hence in the first case, the quantity $\frac{\omega}{\omega_0} - 1$ is calculated for each resonance.

2. Ion Rich Case

In the ion rich cases Deltamode resonances of the cathode sheets are expected since the electron density near the diode walls is low. "Deltamode resonances," the resonances observed on a plasma column, are due to nonuniformity in the plasma. As can be seen from Eq. (3.11), propagation occurs when the applied frequency is greater than the plasma frequency, and the wave is "cut off" when $\omega < \omega_p$. If the frequency is adjusted to be above the plasma frequency at the edge of the column but below that at the center, the wave propagates inward to the point where it is cut off due to the increasing electron density and is reflected. If the total phase shift is 2π when the wave returns to the wall, a standing wave will be set up and resonance results. An excellent analysis of these resonances for the positive column of a discharge is given by Parker.³ Shown in Fig. 3.3 are the rf electric field strengths of the first three modes for the ion rich case corresponding to the dc solutions shown in Figs. 2.11 and 2.13. The first resonance occurs at a frequency below the midplane plasma frequency, and the electric field is

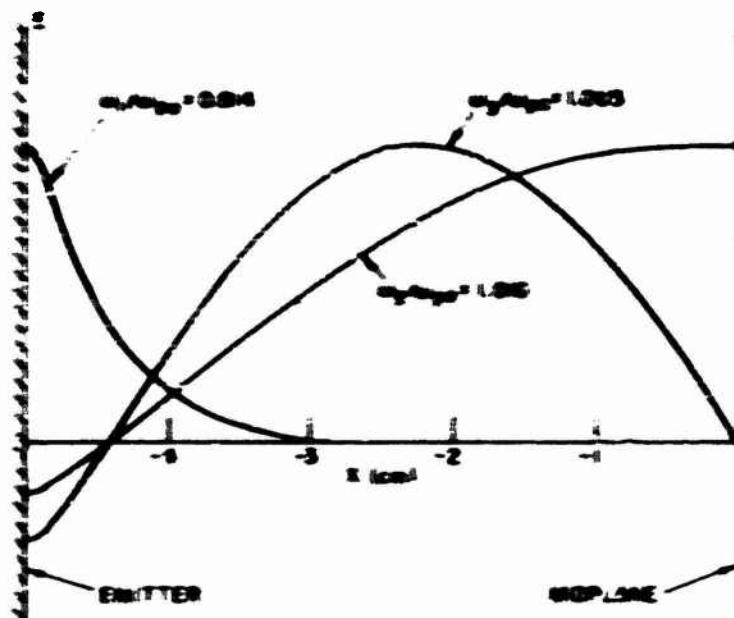

FIG. 3.3. RF ELECTRIC FIELD STRENGTH FOR THE FIRST THREE RESONANCES VS DISTANCE FROM THE MIDPLANE.

concentrated in the sheath region. Clearly this resonance is like the Ditter resonance. The resonance frequency of the second, third and higher order modes are greater than ω_{pe} , and the fields for these penetrate into the plasma. The higher order mode frequencies are very close together and, hence, the modes may not be detectable experimentally. The first and second resonances are spaced far enough apart so that the first resonance may be detectable.

B. END PLATE LOSSES

An electron receives r^2 energy from the electric fields as it traverses the sheath space, but the entire r^2 energy is lost when the electron is absorbed by the wall. In this section, a kinetic model of the plasma is used to study this end plate loss effect.

We shall assume that the plasma is uniform within the sheath. Then the linearized Boltzmann equation for a uniform one-dimensional collisionless electron plasma is given by

$$\frac{d^2}{dx^2} \psi + \frac{1}{x} \frac{d}{dx} \psi_0(x, z, t) = -\frac{\alpha_0 E(x, z, t)}{x} \frac{d\psi}{dx}. \quad (3.11)$$

By Laplace transforming in time, we obtain

$$s^2 \psi_0(s, z, x) + \frac{d\psi_0(s, z, x)}{dx} = -\frac{\alpha_0 E(s, z, x)}{s} \frac{d\psi_0}{dx}, \quad (3.12)$$

where $s = \omega$. The general solution to Eq. (3.12) is given by

$$\psi_0(s, z, x) = C \exp\left[-\frac{E}{s}\right] + \int^x E(s, \xi) \frac{ds}{s^2} \psi_0(s) \exp\left[-\frac{E(x-\xi)}{s}\right] ds. \quad (3.13)$$

For the analysis, we shall use the geometry shown in Fig. 3.-. We shall assume further that $\psi_0(\tau)$ is a symmetric function of τ . In order to make ψ_0 regular for $\text{Re}(s) > 0$, the arbitrary constant in Eq. (3.13) must be selected so that

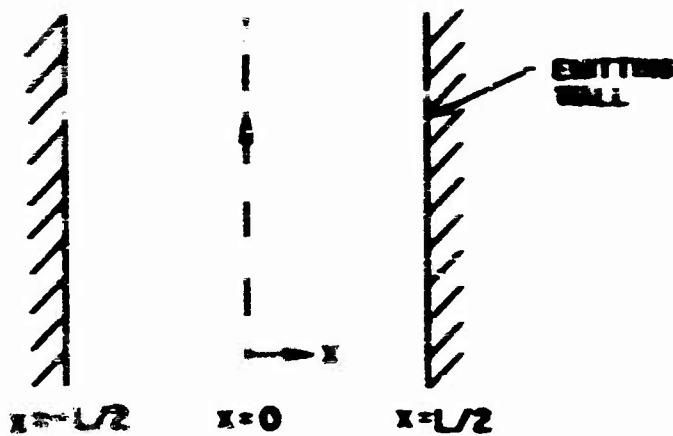

FIG. 3.1. SCATTERING GEOMETRY

$$f_1(p, x, v) = f_1\left(p, -\frac{L}{2}, v\right) \exp\left[-\frac{P(x-L/2)}{v}\right] + \frac{\infty}{\infty} f_0(v) \int_{-L/2}^x R(p, \xi) \exp\left[-\frac{P(x-\xi)}{v}\right] d\xi \quad (3.14)$$

and

$$f_1(p, x, -v) = f_1\left(p, \frac{L}{2}, -v\right) \exp\left[-\frac{P(x-L/2)}{v}\right] - \frac{\infty}{\infty} f_0(v) \int_x^{L/2} R(p, \xi) \exp\left[-\frac{P(x-\xi)}{v}\right] d\xi \quad (3.15)$$

where throughout this section we take $v > 0$. To obtain the boundary condition, we shall assume that a certain fraction $R(v)$ of the particles impinging upon the wall with velocity v is specularly reflected, and the rest perfectly absorbed by the wall. In other words, at $x = -L/2$

$$f_1\left(p, -\frac{L}{2}, v\right) = R(v) f_1\left(p, -\frac{L}{2}, -v\right) \quad (3.16)$$

and at $x = L/2$

$$f_1\left(p, \frac{L}{2}, -v\right) = R(v) f_1\left(p, \frac{L}{2}, v\right) \quad (3.17)$$

The coefficient $E(v)$ can be a complex number which allows for time delay in reflection. By applying these boundary conditions to Eqs. (3.14) and (3.15), one evaluates $I_1(p, \pm L/2, \mp v)$ to obtain

$$I_1(p, x, v) = \frac{\exp\left(\frac{iv}{2}\right)}{\sinh\left(\frac{iv}{2} + \frac{\pi i}{4}\right)} \int_{-L/2}^{L/2} K_0(x - \xi) \exp\left(-\frac{iv\xi}{2}\right) \exp\left(-\frac{iv}{2} \operatorname{erfc}\left(\frac{\xi - x}{\sqrt{v}}\right)\right) d\xi \quad (3.18)$$

and

$$I_1(p, x, -v) = \frac{\exp\left(\frac{iv}{2}\right)}{\sinh\left(\frac{iv}{2} - \frac{\pi i}{4}\right)} \int_x^{L/2} K_0(x - \xi) \exp\left[\frac{iv(x-\xi)}{2}\right] d\xi \quad (3.19)$$

From Maxwell's equation we have

$$\begin{aligned} I_1(p) &= J_1(p, x) + p\epsilon_0 E(p, x) \\ &= p\epsilon_0 E(p, x) - e \int_0^\infty v \left\{ f_1(p, x, v) - f_1(p, x, -v) \right\} dv \end{aligned} \quad (3.20)$$

where the total current density I_1 in the one dimensional system is known to be independent of x . The quantity I_1 represents the driving current which was assumed to be zero in the study of the lossless plasma resonance in Section IIIA. By using Eqs. (3.18) and (3.19), Eq. (3.20) can be expressed in the following form

$$I_1 = p\epsilon_0 E(p, x) + \int_{-L/2}^{L/2} \sigma(|x-\xi|) E(p, \xi) d\xi + \int_{-L/2}^{L/2} \rho(x, \xi) E(p, \xi) d\xi \quad (3.21)$$

The coefficient B_1 can be a complex number which allows for time varying or oscillating. By applying these methods one finds the ϕ_{ext} and ψ_{ext} , the evolution $\psi_{\text{ext}}, \phi_{\text{ext}}$ is given.

$$\frac{\partial}{\partial t} \left[\frac{\partial \psi_{\text{ext}}}{\partial x} - \frac{\partial \phi_{\text{ext}}}{\partial x} \right] = 0$$

$$\frac{\partial}{\partial t} \left[\frac{\partial \psi_{\text{ext}}}{\partial x} \right]$$

$$\frac{\partial}{\partial t} \left[\frac{\partial \phi_{\text{ext}}}{\partial x} - \frac{\partial \psi_{\text{ext}}}{\partial x} \right] = 0$$

$$\frac{\partial}{\partial t} \left[\frac{\partial \phi_{\text{ext}}}{\partial x} \right]$$

From Maxwell's equations we have

$$E_x + iB_x = \omega E_y$$

$$+ \omega E_{y,x} - i \int \omega B_{x,x} - \omega B_{y,y} dx = 0 \quad (1.2)$$

where the real current density J_x of the one-dimensional system is chosen to be independent of x . The quantity E_y represents the driving current which was assumed to be zero at the ends of the lossless plasma waveguide in Lecture 101A. By using Eqs. (1.1) and (1.2) Eq. (1.2) can be expressed as the following form

$$J_x = \omega E_{y,x} + \int_{-L/2}^{L/2} \left(-\omega E_{y,x} - \int_{-L/2}^x \omega B_{x,x} dx \right) dx \quad (1.2)$$

$$= \frac{e^2}{\pi} \int_{-\infty}^{+\infty} \left(1 - \frac{v^2}{c^2} \right)^{-1/2} dv$$

$$= \frac{e^2}{\pi} \int_{-\infty}^{+\infty} \frac{\exp \left[\frac{m^2 v^2}{2c^2} + \frac{mv}{c} \right]}{\left(1 - \frac{v^2}{c^2} \right)^{1/2}} dv$$

$$= \frac{e^2}{\pi} \int_{-\infty}^{+\infty} \frac{\exp \left[\frac{m^2 v^2}{2c^2} + \frac{mv}{c} \right]}{\left(1 - \frac{v^2}{c^2} \right)^{1/2}} dv$$

The quantity $\sigma' = \sigma$ is the conductance factor for an infinite plasma. For the finite density system, the infinite plasma conductance serves as coefficient in an additional reflection term, $\delta \sigma'$.

The problem is now reduced to solving the integral Eq. (1.13) for the electric field. The general solution to this equation for an arbitrary smooth dielectric function is difficult to obtain. In our at case we use the one-particle theory of the plasma resonances. We shall in the following analysis assume that the plasma has spherical shell distribution of velocities as follows:

$$\langle v^2 \rangle = \frac{v_0^2}{2} \langle v^2 \rangle_{v_0} = v_0^2 \quad (1.24)$$

This distribution function when projected into one dimension yields

$$\langle v^2 \rangle = \frac{v_0^2}{2} \quad v = v_0$$

$$= v_0^2 \quad v = v_0 \quad (1.25)$$

By identifying the mean squared velocity to the thermal speed, we obtain the following relation

$$\frac{C}{\pi} \times \frac{\epsilon}{\epsilon_0} = \frac{1}{2} \int_{-L/2}^{L/2} E(x) \cos \left(\frac{\pi x}{L} \right)$$

One important shortcoming of the 'spherical shell' model is that it does not exhibit London damping. However, it does give results which are simple and informative. We shall further simplify the problem by assuming that the reflection coefficient $R = R(\omega)$ is real and independent of ω . By comparing Eq. (3.27) with Eqs. (3.22) and (3.23), it is seen that C_1 and C_2 are found to be

$$C_1 = C_2 = -\frac{\epsilon_0 \epsilon}{2\pi} \cos \left(\frac{\pi L}{2} \right) \quad (3.28)$$

$$E(x) = -\frac{\epsilon_0 \epsilon}{2\pi} \left[\left(\frac{1-R}{1+R} \right) \cos \left(\frac{\pi x}{L} \right) + \left(\frac{R+1}{1+R} \right) \cos \left(\frac{\pi x}{L} \right) \right] \\ - \left[\left(\frac{1-R}{1+R} \right) \cos \left(\frac{\pi x}{L} \right) + \left(\frac{R+1}{1+R} \right) \cos \left(\frac{\pi x}{L} \right) \right] \quad (3.29)$$

With these values of C_1 and C_2 , one can differentiate the integral equation (3.21) twice with respect to x to eliminate the integrals, and obtain the following differential equation

$$\frac{d^2 E(x)}{dx^2} + \left(\frac{1}{L^2} - \frac{\epsilon_0 \epsilon}{\epsilon_0} \right) E(x) = -\frac{I_1}{\epsilon_0} \quad (3.27)$$

with the boundary conditions

$$E\left(-\frac{L}{2}\right) = \frac{I_1}{\epsilon_0 \epsilon} - \frac{\epsilon_0}{L} \left(\frac{1-R}{1+R} \right) \frac{dE(x)}{dx} \Bigg|_{x = -\frac{L}{2}} \quad (3.29)$$

and

$$E\left(\frac{L}{2}\right) = \frac{I_1}{\epsilon_0 \epsilon} - \frac{\epsilon_0}{L} \left(\frac{1-R}{1+R} \right) \frac{dE(x)}{dx} \Bigg|_{x = \frac{L}{2}} \quad (3.30)$$

where now ρ is replaced by λ . The solution to Eq. 3.2⁰ which satisfies Eqs. 3.2⁰ and 3.3⁰ is given by

$$E'z = \frac{I_1}{\omega c_0(1 - \frac{\rho^2}{z^2})} \left[1 - \frac{\frac{\rho^2}{z^2} \frac{d^2}{dz^2} \cos \frac{\lambda z}{2}}{\cos \frac{\lambda z}{2} + i(\frac{1-\rho^2}{1+\rho^2}) \frac{d}{dz} \left(1 - \frac{\rho^2}{z^2} \frac{d^2}{dz^2} \sin \frac{\lambda z}{2} \right)} \right] \quad 3.2$$

where $\frac{d^2}{dz^2} = \frac{\partial^2}{\partial z^2} - \frac{\partial^2}{\partial r^2}$. The field consists of a capacitive part and a space-varying part. When $\rho = 1$, λ is real and the space-varying part varies sinusoidally in space.

The impedance of the duct is obtained by differentiating Eq. 3.2.

$$\begin{aligned} Z_{in} &= -\frac{V}{I_1} = \int_{-L/2}^{L/2} \frac{E'z}{I_1} dz \\ &= \frac{1}{\omega c_0(1 - \frac{\rho^2}{z^2})} \left[1 - \frac{\frac{\rho^2}{z^2} \frac{d^2}{dz^2} \sin \frac{\lambda z}{2}}{\cos \frac{\lambda z}{2} + i(\frac{1-\rho^2}{1+\rho^2}) \frac{d}{dz} \left(1 - \frac{\rho^2}{z^2} \frac{d^2}{dz^2} \sin \frac{\lambda z}{2} \right)} \right] \end{aligned} \quad 3.3$$

For the special case of perfect reflection at the walls, $R = 1$, the impedance is given by

$$Z = \frac{1}{\omega c_0(1 - \frac{\rho^2}{z^2})} \left[1 - \frac{\frac{\rho^2}{z^2}}{\frac{1}{2} \tan \frac{\lambda z}{2}} \right] \quad 3.3$$

which is the result obtained by Hall.¹

Shown in Figs. 3.5 and 3.6 are the real and imaginary parts of the impedance for different values of R . Note that, when $R = 1$, resonances occur whenever $\lambda L/2 = (2n+1)\pi/2$ where n is an integer. However, with $R = 0$ these resonances disappear except for the lowest order one. Since the spherical shell model does not exhibit Landau damping, the loss in this case can be attributed entirely to the end plate absorption, and the "Q" of the resonance is directly related to the reflection coefficient R .

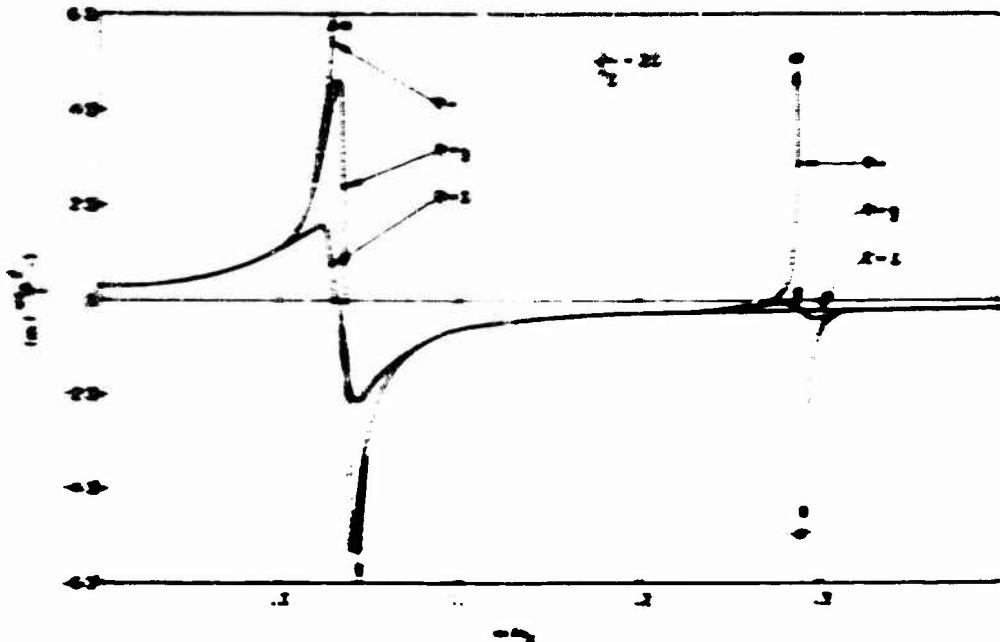

FIG. 3.5. THE IMAGINARY PART OF THE NORMALIZED NOISE RESPONSE
VERSUS w . The parameter for the plots is the reflection coefficient γ .

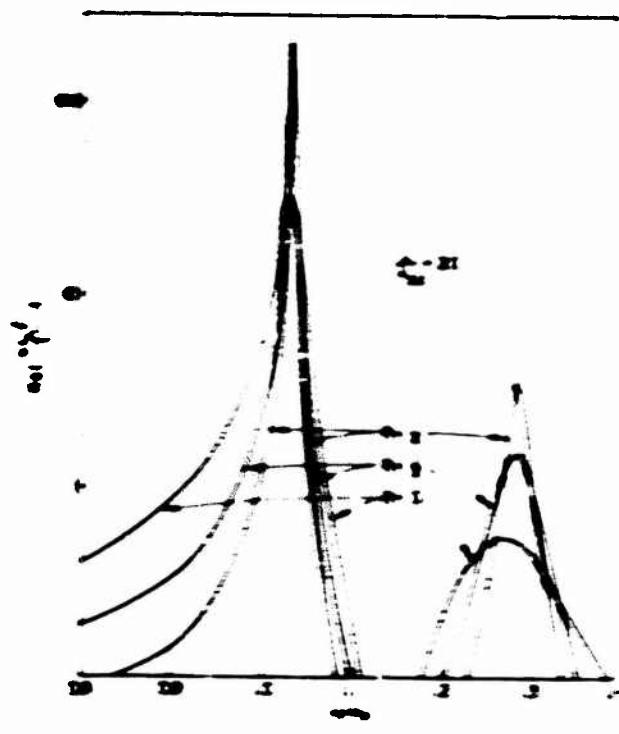

FIG. 3.6. THE REAL PLOT OF THE NORMALIZED NOISE
RESPONSE VERSUS w .

It is of interest to compare the diode impedance with that of a somewhat similar system having a pair of parallel plane grids immersed in an infinite plasma. By assuming that the grids intercept field lines but not the particles, the impedance between the pair of grids can be obtained by the method described by Simon. For grids separated by a distance L and immersed in a plasma with a spherical shell velocity distribution, the impedance is found to be

$$Z'_{\parallel} = \frac{L}{\ln \left(1 + \frac{c^2}{v_0^2} \right)} \left[1 - \frac{c^2}{v_0^2} \rightarrow - \frac{c^2}{v_0^2} \frac{\sin \frac{cL}{v_0}}{\frac{cL}{v_0}} \right] \quad (3.34)$$

where v_0 is as defined previously. Shown in Fig. 3.7 is the impedance as a function of c . The impedance of the parallel grids differs from

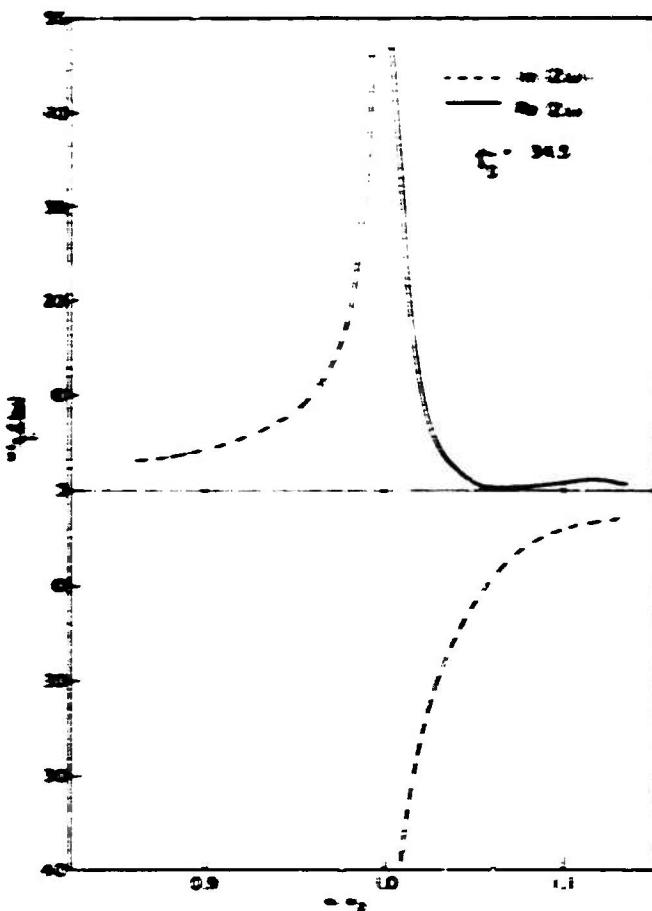

FIG. 3.7. NORMALIZED IMPEDANCE FOR A PAIR OF INFINITE GRIDS IMMersed IN AN INFINITE PLASMA.

the diode impedance in several respects. First, the grid system exhibits resonance at the plasma frequency while the resonance for the diode is shifted above ω_p . Also, the grid impedance is infinite at $\omega = \omega_p$, while the diode impedance has poles along the real ω axis only when $R = 1$. Another difference is that the impedance of the grids is purely imaginary for frequencies below the plasma frequency while the diode impedance, except for the case of $R = 1$, is complex for all frequencies. The loss in the grid system is attributed to the energy carried away by the waves from the grid region to the external region.

C. CONCLUDING REMARKS

Electrostatic resonances in a nonuniform plasma diode are predicted by using the hydrodynamic model and a fictitious boundary condition. These resonances probably will be modified greatly when kinetic models are used to study the diode. The analysis of a uniform plasma diode using the spherical shell velocity distribution shows that wall absorption plays an important role in the determination of the diode impedance. In fact, when complete absorption occurs at the walls, the only resonance of significance occurs when the diode separation is exactly equal to a half-wavelength. Because of the absorption effect, resonances are not found when multiples of half-wavelength "fit" into the diode space. Thus, some of the resonances predicted by the hydro-dynamic model may not be observable, especially those found in the electron-rich diode where all of the electron trajectories hit the wall. (See the phase diagram of Fig. 2.2). However, the resonances predicted for the ion-rich case may be observable since most of the electrons in this case are trapped in the diode space and do not strike the wall.

Neither the hydrodynamic model nor the spherical shell model is capable of exhibiting the Landau damping effect. An analysis employing a more realistic gaussian velocity distribution will further modify the resonances and the impedances.

IV. DC THEORY OF CYLINDRICAL BOX MAGNETOPLASMA

In Chapter II we studied the dc properties of plasma confined between infinite planes. In a practical system the infinite system can only be approximated crudely. Most of the plasma devices which use the contact ionization process consist of circular emitters which face each other coaxially but are separated by a distance many times greater than the diameter of the emitters. The radial confinement of the plasma in such a system is achieved by the axial magnetic field. In this chapter we investigate the dc properties of a cylindrical column of magnetoplasma. First, a theoretical analysis will be given followed by some dc measurement results on the cylindrical column.

A CYLINDRICALLY SYMMETRIC SOLUTION TO THE BOLTZMANN EQUATION

The Boltzmann equation for the j^{th} species of the plasma in electric and magnetic fields is given by

$$\frac{\partial f_j}{\partial t} + \vec{v} \cdot \frac{\partial f_j}{\partial \vec{r}} + \frac{e_j}{m_j} (\vec{E} + \vec{v} \times \vec{B}) \cdot \frac{\partial f_j}{\partial \vec{v}} = \left(\frac{\partial f_j}{\partial t} \right)_{coll}. \quad (4.1)$$

We seek a steady state solution ($\partial/\partial t = 0$) to the Boltzmann equation under the assumption of negligibly small collision terms. In other words,

$$\vec{v} \cdot \frac{\partial f_j}{\partial \vec{r}} + \frac{e_j}{m_j} (\vec{E} + \vec{v} \times \vec{B}) \cdot \frac{\partial f_j}{\partial \vec{v}} = 0. \quad (4.2)$$

We shall assume further that the plasma is cylindrically symmetric ($\partial/\partial \theta = 0$) and uniform in the direction of the externally applied dc magnetic field ($\partial/\partial z = 0$). Any function of the constants of the motion, such as the total energy, satisfies Eq. (4.2). One such solution is given by⁴³

$$f_j(\vec{v}, \vec{r}) = f_{0j} \left[-\frac{e_j}{2} \vec{v} \cdot \vec{v}_j + \vec{v}_j \cdot \vec{v} + \frac{e_j}{m_j} \vec{v}_j \cdot \vec{r} - \vec{A} \cdot \vec{v}_j - \frac{e_j}{m_j} \vec{v} \cdot \vec{r} \right] \quad (4.3)$$

where $\vec{E}_j = \vec{i}_z \omega_j$ is a vector along the magnetic field, \vec{r} is the coordinate vector perpendicular to the magnetic field, $\vec{A}(\vec{r})$ is the vector potential, and $V(\vec{r})$ is the scalar potential. As can be seen, Eq. (4.3) is given in terms of the total energy and the total angular momentum which are constants of motion. The electric and magnetic fields can be derived from $V(\vec{r})$ and $\vec{A}(\vec{r})$ by

$$\vec{B} = \vec{\nabla} \times \vec{A}(\vec{r}) ;$$

$$\vec{E} = -\vec{\nabla} V(\vec{r}) .$$

We shall prescribe the solution to have Maxwellian velocity distribution along the axis, and, hence,

$$f_j(\vec{v}, \vec{r}) = A_j \exp \left[\frac{m_j}{kT_j} \left(-\frac{v^2}{2} + \vec{v} \cdot (\vec{\omega}_j \times \vec{r}) + \frac{e_j}{m_j} (\vec{\omega}_j \times \vec{r}) \cdot \vec{A}(\vec{r}) - \frac{e_j}{m_j} V(\vec{r}) \right) \right] . \quad (4.4)$$

By assuming further that the diamagnetic field produced by the plasma rotation has negligible effect on the dc magnetic field, the vector potential becomes

$$\vec{A} = \vec{B}_0 \times \vec{r}$$

and Eq. (4.4) can be reduced to

$$f_j(\vec{v}, \vec{r}) = A_j \exp \left[\frac{m_j}{kT_j} \left(-\frac{v^2}{2} + \vec{v} \cdot (\vec{\omega}_j \times \vec{r}) + \frac{\omega_j \omega_{cj} r^2}{2} - \frac{e_j}{m_j} V(\vec{r}) \right) \right] \quad (4.5)$$

where $\omega_{cj} = |e_j B_0| / m_j$ is the cyclotron frequency of the j^{th} species. Equation (4.5) can be rewritten as

$$f_j(\vec{v}, \vec{r}) = A_j \exp \left[\frac{m_j}{kT_j} \left(-\frac{[\vec{v} - \vec{\omega}_j \times \vec{r}]^2}{2} + \frac{[\omega_{cj}^2 + \omega_j \omega_{cj}]}{2} r^2 - \frac{e_j}{m_j} V(\vec{r}) \right) \right] . \quad (4.6)$$

From Eq. (4.6) we can see that the whole species rotates as a solid body with rotational frequency ω_j .

When Eq. (4.6) is specialized for electrons and ions, we have

$$f_{oi}(\vec{v}, \vec{r}) = A_i \exp\left[\frac{m_i}{kT_i} \left(-\frac{[\vec{v} - \vec{\omega}_i \times \vec{r}]^2}{2} + \frac{[\omega_i^2 + \omega_i \omega_{ci}]}{2} r^2 - \frac{eV(r)}{m_i} \right) \right] \quad (4.7)$$

and

$$f_{oe}(\vec{v}, \vec{r}) = A_e \exp\left[\frac{m_e}{kT_e} \left(-\frac{[\vec{v} - \vec{\omega}_e \times \vec{r}]^2}{2} + \frac{[\omega_e^2 - \omega_e \omega_{ce}]}{2} r^2 + \frac{eV(r)}{m_e} \right) \right]. \quad (4.8)$$

The density profiles and the current densities can be obtained by performing the appropriate integration of Eqs. (4.7) and (4.8).

$$n_e(r) = n_e(0) \exp\left[\frac{m_e}{kT_e} \left(\frac{[\omega_e^2 - \omega_e \omega_{ce}]}{2} r^2 + \frac{e}{m_e} V(r) \right) \right], \quad (4.9)$$

$$n_i(r) = n_i(0) \exp\left[\frac{m_i}{kT_i} \left(\frac{[\omega_i^2 + \omega_i \omega_{ci}]}{2} r^2 - \frac{e}{m_e} V(r) \right) \right], \quad (4.10)$$

$$\vec{J}_e = -e(\vec{\omega}_e \times \vec{r})n_e(r), \quad (4.11)$$

$$\vec{J}_i = e(\vec{\omega}_i \times \vec{r})n_i(r). \quad (4.12)$$

For the special case of complete neutrality, the simple solution yields a gaussian density profile with mean squared radius

$$r_m^2 = -\frac{2kT_i}{m_i(\omega_i^2 + \omega_i \omega_{ci})} = \frac{-2kT_e}{m_e(\omega_e^2 - \omega_e \omega_{ce})} \quad (4.13)$$

and the electrons and ions each rotate as a solid body about the axis with frequencies ω_e and ω_i respectively. The following restrictions must be placed on ω_e and ω_i to avoid densities which rise with increasing r .

$$\omega_{ce} < \omega_1$$

$$\omega_1 < \omega_{ce}$$

Since ω_{ce} and ω_{ce} are defined to be positive, the rotational vector $\vec{\omega}_1 = \omega_1 \hat{z}_1$ is anti-parallel to the magnetic field and $\vec{\omega}_e = \omega_e \hat{z}_e$ is parallel to the magnetic field. The above conditions restrict τ_{\perp}^2 to

$$\tau_{\perp}^2 = \frac{\omega_1^2}{\omega_{ce}^2}$$

By using Eq. (4.11), the rotational frequencies ω_1 and ω_e can be obtained in terms of τ_{\perp}^2 as follows

$$\omega_1 = \sqrt{\frac{\omega_{ce}^2 + \omega_{ce}^2 - 4\omega_{ce}^2 \sin^2 \theta_{ce}}{2}}$$

$$\omega_e = \sqrt{\frac{\omega_{ce}^2 + \omega_{ce}^2 - 4\omega_{ce}^2 \sin^2 \theta_{ce}}{2}}$$

There are two possible rotational frequencies for a given value of τ_{\perp}^2 for each species.

Under the assumption of neutrality, the self-magnetic fields can be computed from \vec{J}_1 and \vec{J}_e by using Ampere's law. The density profile for the neutral case is given by $n(r) = n_0 e^{-r^2/\lambda^2} \exp(-r^2/\lambda^2)$ and hence, the total azimuthal current obtained from Eqs. (4.11) and (4.12) is

$$I_{\text{total}} = C_{\text{tot}} \cdot \omega_e \cdot \tau_{\perp}^2 \exp(-\frac{r^2}{\lambda^2}) \quad (4.17)$$

From Ampere's law, the following relation is obtained for the z-component of the magnetic field

$$\begin{aligned} B_z &= \mu_0 I_{\text{total}} + \omega_1 \int_0^r \frac{1}{2} \exp\left(-\frac{r^2}{\lambda^2}\right) dr \\ &= \frac{\omega_1 \tau_{\perp}^2 \lambda^2 - \omega_1}{2} \exp\left(-\frac{r^2}{\lambda^2}\right). \end{aligned} \quad (4.18)$$

Comparing this field with $\mathbf{v}_1 \times \mathbf{B}_1$, we have

$$\frac{\omega_0 E_{\perp}^2}{B_1^2} = \frac{e^2 n_e^2}{m_e c^2} B_1^2 - v_{te}^2 \cos^2\left(\frac{\theta}{2}\right) \quad (4.19)$$

where c is the speed of light. Thus, the self-magnetic field can be ignored if

$$\frac{e^2 n_e^2}{m_e c^2} B_1^2 - v_{te}^2 < 1 \quad (4.20)$$

One way to minimize the left-hand side of (4.20) is to choose the smaller of the two possible rotational frequencies for each species given by Eqs. (4.11) and (4.12). In other words,

$$\frac{\omega_{te}^2 - e^2 n_e^2 - 1043 \frac{e^2 n_e^2}{m_e c^2}}{m_e c^2} \quad (4.21)$$

$$\frac{\omega_{ti}^2 - e^2 n_i^2 - 1043 \frac{e^2 n_i^2}{m_i c^2}}{m_i c^2} \quad (4.22)$$

Later we shall assume that v_{te} takes the minimum value allowed by the inequality of (4.21). For most a special case the inequality of (4.21) becomes

$$\frac{\omega_{te}^2 - e^2 n_e^2}{m_e c^2} \quad (4.23)$$

where v_{te} is the ion thermal speed. Many laboratory plasmas satisfy such an inequality.

The elementary solution obtained in this section can be used to construct more complicated solutions appropriate for a given plasma. In the following section we will consider some solutions synthesized from the elementary one.

B. SUPERPOSITION OF ROTATING CLOUDS

An example of a more complicated solution to the Boltzmann equation for the i^{th} species is

$$f_i(\vec{r}, \vec{v}) = \int d\vec{\xi} f_i(\vec{\xi}) \exp \left[-\frac{n_i}{kT_i} \left(-\frac{[\vec{v} - \vec{\omega}_i \times \vec{r}]^2}{2} + \frac{\vec{\omega}_i^2 + \omega_i^2 c_i^2}{2} r^2 - \frac{e_i V(r)}{n_i} \right) \right] \quad (-.24)$$

which is a superposition of rotating clouds with different rotational frequencies. A valid solution is given by

$$f_i(\vec{r}, \vec{v}) = \int d\vec{\xi} F(\vec{\xi}) \exp \left[-\frac{n_i}{kT_i} \left(-\frac{[\vec{v} - \vec{\omega}_i \times \vec{r}]^2}{2} + \frac{\vec{\omega}_i^2 + \omega_i^2 c_i^2}{2} r^2 - \frac{e_i V(r)}{n_i} \right) \right]. \quad (-.25)$$

We have not found a practical system which can be described by Eqs. (.24) and (.25).

C. SUPERPOSITION OF DISPLACED ELEMENTARY SOLUTIONS

Under the assumption of complete neutrality, a more interesting type of solution is obtained. Such a solution is

$$f_i(\vec{r}, \vec{v}) = A \int d\vec{\xi} F(\vec{\xi}) \exp \left[\frac{n_i}{kT_i} \left(-\frac{[\vec{v} - \vec{\omega}_i \times (\vec{r} - \vec{\xi})]^2}{2} + \frac{\omega_i^2 + \omega_i^2 c_i^2}{2} (\vec{r} - \vec{\xi})^2 \right) \right] \quad (4.26)$$

where $\vec{\xi}$ is a vector in the r, θ plane. Equation (4.26) is just the convolution of the elementary solution and the "displacement" function $F(\vec{\xi})$. Equation (4.26) satisfies the Boltzmann equation, but there is no way to handle the non-neutral cases in representation. The self-magnetic field will also spoil the solution. To insure neutrality the distribution function for the electrons must be of the form

$$f_e(\vec{r}, \vec{v}) = A \int d\vec{\xi} F(\vec{\xi}) \exp \left[\frac{m_e}{kT_e} \left(- \frac{\{\vec{v} - \vec{\omega}_e \times (\vec{r} - \vec{\xi})\}^2}{2} \right. \right. \\ \left. \left. + \frac{\omega_e^2 - \omega_e \omega_{ce}}{2} \right) \{\vec{r} - \vec{\xi}\}^2 \right] . \quad (4.27)$$

where the rotational frequency ω_e is related to ω_i by Eq. (4.13).

An example of $F(\vec{\xi})$, which may be applicable to a practical situation, is

$$F(\vec{\xi}) = 1 \quad \text{for } 0 < |\vec{\xi}| < b_o \\ = 0 \quad \text{for } |\vec{\xi}| > b_o . \quad (4.28)$$

This is expected to give a solution which closely approximates a plasma produced between two circular diode plates of radius b_o and confined by an axial magnetic field. For ions the expressions for the density profile and the current density become

$$N_i(r) = \frac{2N_o}{\pi r_o^2 r_m^2} \int_0^{b_o} \xi I_0 \left(\frac{2r\xi}{r_m^2} \right) \exp \left[- \frac{(r^2 + \xi^2)}{r_m^2} \right] d\xi , \quad (4.29)$$

$$J_{\theta i}(r) = \frac{2\omega_i N_o e}{\pi r_o^2 r_m^2} \int_0^{b_o} \left\{ r\xi I_0 \left(\frac{2r\xi}{r_m^2} \right) - \xi^2 I_1 \left(\frac{2r\xi}{r_m^2} \right) \right\} \exp \left[- \frac{(r^2 + \xi^2)}{r_m^2} \right] d\xi \quad (4.30)$$

where $J_{\theta i}(r)$ is the θ component of the ion current density, I_0 and I_1 are zero- and first-order modified Bessel functions of the first kind, N_o is the number of particles per unit length, and r_m is as defined in Eq. (4.13). From Eqs. (4.27) and (4.28), the electron density and current profiles can be obtained and are found to be related to $N_i(r)$ and $J_{\theta i}(r)$ in the following manner

$$N_e(r) = N_i(r) \quad (4.31)$$

$$J_{\theta e}(r) = - \frac{\omega_e}{\omega_i} J_{\theta i}(r) \quad (4.32)$$

Equations (4.29) and (4.30) can be integrated readily numerically, and the results for $\omega_i = -\omega_{ci}/2$ are shown in Figs. 4.1, 4.2, and 4.3. The rotational frequency ω_i is arbitrary, but the choice of $\omega_i = -\omega_{ci}/2$ gives a solution with best confinement (smallest mean radius). In the figures the parameter varied for the plots is

$$r_m = \sqrt{\frac{8\kappa T_i}{m_i \omega_{ci}^2}} \quad (4.33)$$

The graphs show what we expect of a magnetically confined plasma as the magnetic field is varied. The density profile becomes flat-topped as the magnetic field is increased and, at infinite magnetic field, the profile becomes perfectly flat-topped with a sharp boundary. In general, the density drop at the plasma edge occurs roughly within a distance of $2r_m$. The current density is highest where the density gradient is highest. The ion drift velocity is of the order of the ion thermal velocity at the plasma edge. Solving Eqs. (4.21) and (4.22) for ω_e under the condition of $T_i = T_e$ and $\omega_i = -\omega_{ci}/2$, we find $\omega_e \approx \omega_{ci}/4 = -\omega_i/2$.

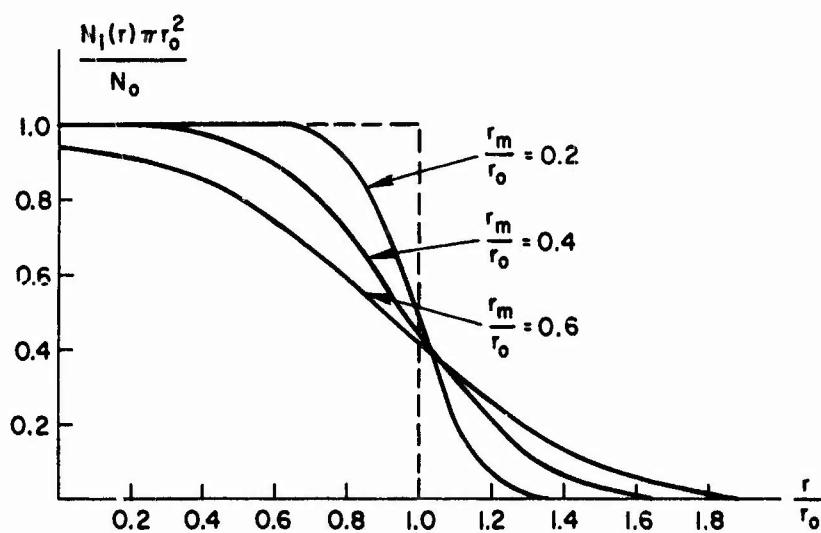

FIG. 4.1. DENSITY PROFILE. Normalized density is plotted versus normalized radius for different values of $r_m = \sqrt{8\kappa T_i / (m_i \omega_{ci}^2)}$.

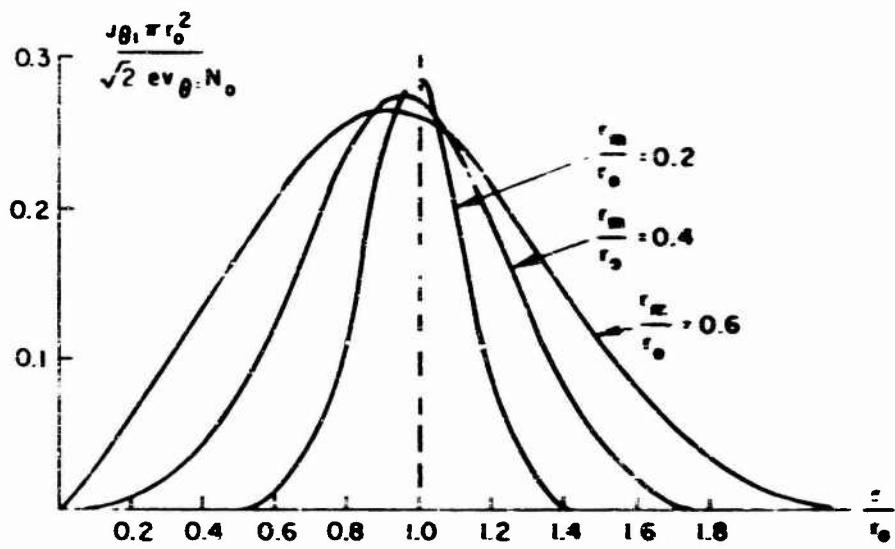

FIG. -2. ION CURRENT DENSITY. The $\frac{1}{r}$ component of the ion current density is normalized to $\frac{J_{\theta_1} \pi r_0^2}{\sqrt{2} e v_{\theta_1} N_0}$ and plotted vs r/r_0 .

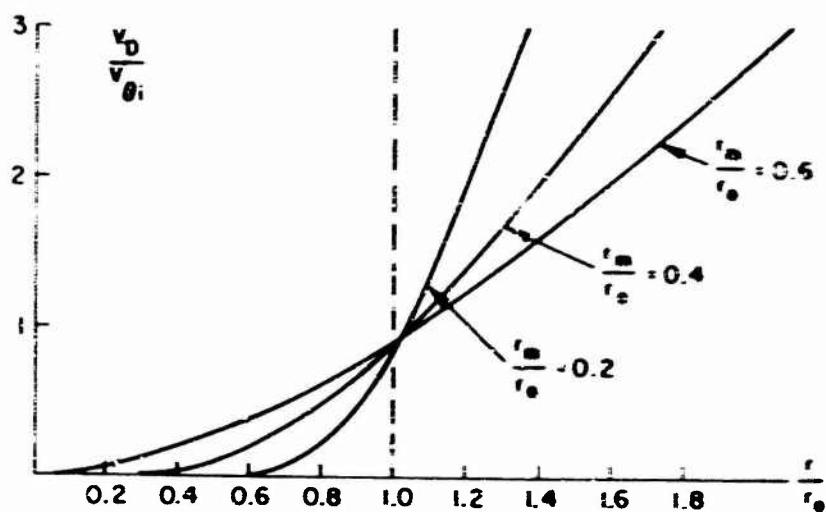

FIG. -3. NORMALIZED ION DRIFT VELOCITY VS r/r_0 . The drift velocity is normalized to the ion thermal velocity v_{θ_1} .

Thus, the electron drift velocity is also of the order of the ion drift velocity, and, hence, negligibly small when compared to the electron thermal velocity.

W. H. Cutler³⁹ has derived an expression very similar to Eq. (4.29) but with an entirely different method. After approximation Cutler arbitrarily sets

$$\frac{r^2}{n} = \frac{-eT_i}{\pi^2 c_i}$$

This value does not satisfy the inequality (4.1-) for real ω_i and, hence, is disallowed in our theory.

D. EXPERIMENTAL MEASUREMENTS OF DC DENSITY AND DRIFT PROFILES

In the sodium plasma produced in the manner described in Chapter II E, we attempted to measure the azimuthal electron drift and the density profile. For the measurement a modified Langmuir probe is used. The tip of this probe is shown in Fig. 4.4. It can be rotated so that the dc density profile can be measured by facing the probe surface toward the buttons, while plasma rotation may be measured by facing the probe surface in the azimuthal direction. The detailed circuitry and the probe technique used to overcome various problems is discussed in Appendix A.

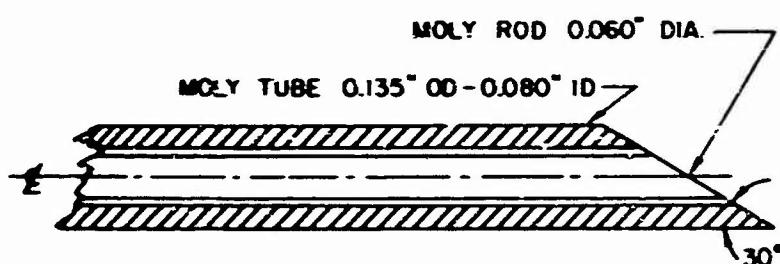

FIG. 4.4. LANGMUIR PROBE

With the collecting surface facing the azimuthal direction, the probe curve is obtained first with the magnetic field directed one way and then with the magnetic field reversed. Presumably the azimuthal drift can be detected by noting the differences in the probe current for the two cases. Shown in Fig. 4.5 is a typical set of probe curves in the magnetic field. As the probe potential is increased from some negative value, the current rises exponentially and, at the plasma potential, breaks away from the exponential rise to form a "knee." We have plotted in Fig. 4.6 the current at the "knee" versus radius. There is a significant difference in the probe current when the magnetic field is reversed, indicating that an azimuthal drift is present. However, due to the lack of an appropriate probe theory, the measured result cannot be quantitatively related to the azimuthal drift. A similar measurement for ion drift is desirable, but considerable improvement on the probe circuits is required first since the ion currents are of the order of the leakage current or less.

At 180 gauss, the radius r_m as defined by Eq. (4.32) is 3 cm. This value is much too high to give current density profiles such as those of Fig. 4.6. Comparison of theoretical density profile was also made with the experimental density profile of a plasma produced in a similar manner by Cutler.³⁹ There again we found that invariably the experimental

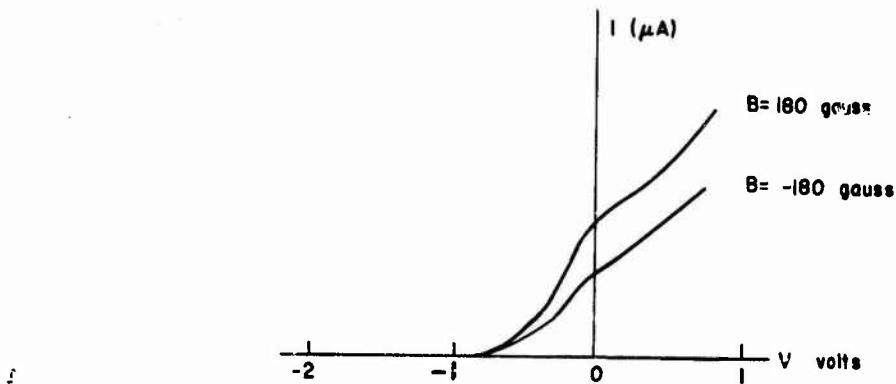

FIG. 4.5. TYPICAL SET OF PROBE CURVES. The two curves are obtained by keeping the probe in the identical position but by changing the direction of the magnetic field.

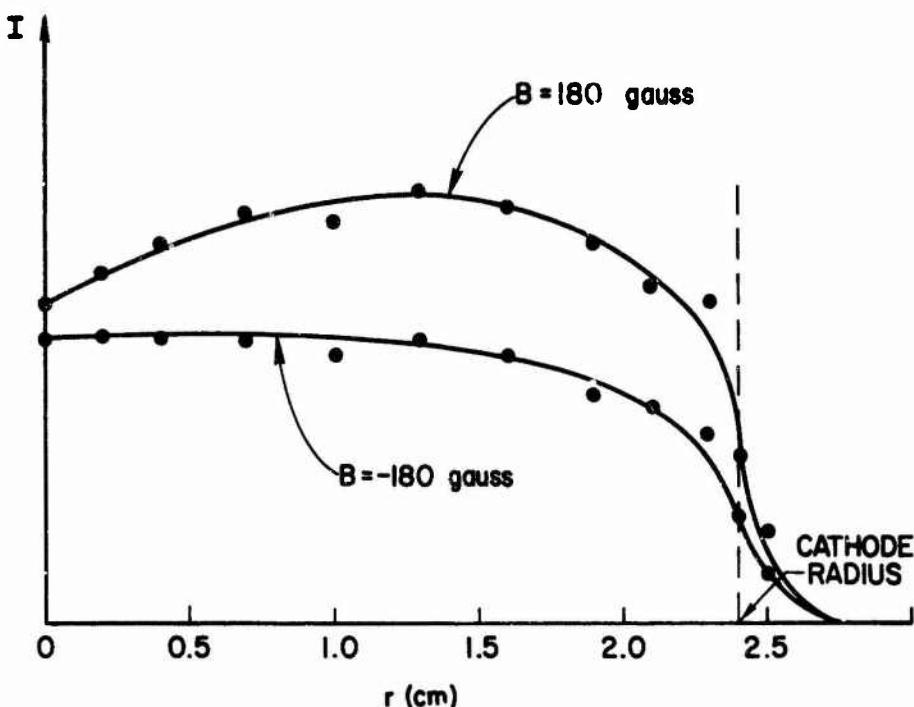

FIG. 4.6. AZIMUTHAL PROBE CURRENT VS RADIAL DISTANCE. The two curves are obtained with identical but oppositely directed magnetic fields. The parameters of the experimental plasma were: $T = 1800^{\circ}\text{K}$; $n = 3 \times 10^6/\text{cc}$; $\lambda_0 = 1.7\text{ mm.}$

density profile had a much sharper drop at the plasma edge than the theoretical profile. The discrepancy emphasizes the importance of the electric field which we have ignored in our theory. The electric field may be set up in the following manner. The primary electrons supplied within the solid cylinder, due to their small Larmor radii, have a sharper boundary than the ions. Hence, charge separation occurs and an electric field is set up which pulls the electrons outward and ions inward. Since the probe measures the electron current, it is not surprising that the profile is sharper than that predicted by a theory which assumes complete neutrality. Indeed, measurements show that there is an electric field present, though not concentrated near the plasma edge as might be expected. Shown in Fig. 4.7 is the potential profile of the column. An electric field of approximately 0.25 volts/cm is present.

For the study of waves along a plasma column undertaken in Chapter VI, we shall assume that the plasma column is uniform with a sharp

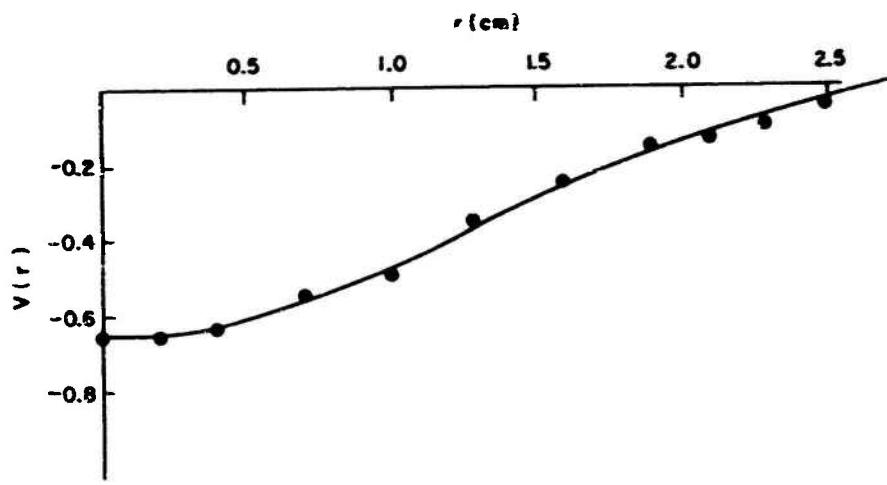

FIG. 4.7. POTENTIAL PROFILE.

boundary, and that there is no azimuthal drift. The results of this chapter serve to point out the range of validity of the dc model used in the rf analysis.

V. WAVES IN AN INFINITE MAGNETOPLASMA

In this chapter we investigate the waves in an infinite uniform hot magnetoplasma keeping in mind our final goal of obtaining results for a finite cylindrical plasma column. We are primarily concerned with the derivation of the dielectric tensors which describe the plasma behavior. We will demonstrate a new method to separate the plasma conduction current into polarization and magnetization currents. The separation is found to simplify the analysis considerably.

A. THE DIELECTRIC TENSOR IN A MAXWELLIAN ELECTRON PLASMA

Let us consider the linearized collisionless Boltzmann equation for the electrons. For the moment we shall assume that the ions are infinitely heavy. Then the zero and first order equations are given by

$$(\vec{v} \times \vec{B}_0) \cdot \frac{\partial f_0}{\partial \vec{v}} = 0, \quad (5.1)$$

$$\frac{\partial f_1}{\partial t} + \vec{v} \cdot \frac{\partial f_1}{\partial \vec{x}} - \frac{e}{m} [\vec{v} \times \vec{B}_0] \cdot \frac{\partial f_1}{\partial \vec{v}} = \frac{e}{m} [\vec{E}_1(\vec{x}, t) + \vec{v} \times \vec{B}_1(\vec{x}, t)] \cdot \frac{\partial f_0}{\partial \vec{v}} \quad (5.2)$$

where $f_1 = f_1(t, \vec{x}, \vec{v})$. By Fourier transforming in \vec{x} and Laplace transforming in t , Eq. (5.2) is reduced to

$$(i\omega - i\vec{k} \cdot \vec{v})f_1 - \frac{e}{m} [\vec{v} \times \vec{B}_0] \cdot \frac{\partial f_1}{\partial \vec{v}} = \frac{e}{m} (\vec{E} + \vec{v} \times \vec{B}) \cdot \frac{\partial f_0}{\partial \vec{v}} \quad (5.3)$$

where now $f_1 = f_1[\omega, \vec{k}, \vec{v}]$. We introduce the following gyro-tensor

$$\vec{D}(\varphi) = \vec{n} \vec{n} + (I - \vec{n} \vec{n}) \cos \varphi - \vec{n} \times I \sin \varphi \quad (5.4)$$

and its integral

$$\begin{aligned} \vec{L}(\varphi) &= \int_0^\varphi \vec{D}(\varphi') d\varphi' \\ &= \vec{n} \vec{n} \varphi + (I - \vec{n} \vec{n}) \sin \varphi + \vec{n} \times I (\cos \varphi - 1) \end{aligned} \quad (5.5)$$

where \vec{n} is a unit vector in the direction of the magnetic field and "I" is the unit tensor. The detailed derivation of the solution to Eq. (5.3) is given in Appendix B. The solution is found to be

$$f_1[\omega, \vec{k}, \vec{v}] = \frac{e}{m\omega_c} \int_0^\infty \exp\left[\frac{i\omega\varphi}{\omega_c} + i \frac{\vec{k} \cdot \vec{L} \cdot \vec{v}}{\omega_c}\right] \vec{E} \cdot \vec{D} \cdot \frac{\partial f}{\partial \vec{v}} d\varphi. \quad (5.6)$$

This solution can be verified by substituting it directly into Eq. (5.3).

The above solution agrees with those given by Fried⁴⁴ and Stix.¹³ Through the use of the gyrotensors $\vec{D}(\varphi)$ and $\vec{L}(\varphi)$, our solution appears in a much simpler form than that given by Stix. The current density can be obtained by the integration

$$\langle \vec{p}_v \rangle = -e \int \vec{v} f_1[\omega, \vec{k}, \vec{v}] d^3 v. \quad (5.7)$$

In Appendix C we show that it is possible to separate the current density into polarization and magnetization currents, as suggested by Lorentz's electron theory of matter, i.e.

$$\langle \vec{p}_v \rangle = i\omega \vec{P} - ik \times \vec{M} \quad (5.8)$$

where $\vec{D} = \epsilon_0 \vec{E} + \vec{P}$ and $\vec{B} = \mu_0 (\vec{H} + \vec{M})$. For a Maxwellian plasma we obtain (see Appendices D and E),

$$\vec{P} = -\frac{\epsilon_0 \omega_p^2}{\omega_c^2} \int_0^\infty \exp\left[-\frac{i\omega\varphi}{\omega_c} - \frac{v_\theta^2}{2\omega_c^2} (\vec{k} \cdot \vec{L})^2\right] \vec{L}(-\varphi) \cdot \vec{E} d\varphi \quad (5.9)$$

and

$$\vec{M} = \frac{i\omega v_\theta^2}{\omega_c^2 \mu_0} \int_0^\infty \vec{\mu}(\varphi) \cdot \vec{B} \exp\left[-\frac{i\omega\varphi}{\omega_c} - \frac{v_\theta^2}{2\omega_c^2} (\vec{k} \cdot \vec{L})^2\right] d\varphi \quad (5.10)$$

where

$$\vec{\mu}(\varphi) = (I - \vec{n}\vec{n})\varphi \sin \varphi + (\vec{n} \times I)\varphi(1 - \cos \varphi) + 2\vec{n}\vec{n}(1 - \cos \varphi)$$

The importance of separating the current density into the two parts is realized when we deal with boundary conditions in a finite plasma. Without the vectors \vec{P} and \vec{E} , it is necessary to work with surface charges and surface currents at the boundary. Such a task is very difficult, if not impossible, for a hot plasma boundary.

From Eq. (5.9) the electric susceptibility tensor $\vec{\chi}$, as well as the dielectric tensor $\vec{\epsilon}$, can be obtained from the following relation

$$\vec{D} = \epsilon_0 \vec{\epsilon} \cdot \vec{E} + \epsilon_0 \vec{E} \times \vec{P} = \epsilon_0 [I + \vec{\chi}] \cdot \vec{E}.$$

We shall be concerned primarily with the dielectric properties of the plasma, since we are interested in electrostatic waves in which the magnetic energy is negligibly small. The dielectric tensor can be expressed in the following form

$$\vec{\epsilon} = \begin{bmatrix} \epsilon_{xx} & \epsilon_{xy} & : \\ \epsilon_{yx} & \epsilon_{yy} & : \\ : & : & \epsilon_{zz} \end{bmatrix}$$

with

$$\epsilon_{yy} = \epsilon_{xx} = 1 + \frac{\omega_p^2}{\omega_c^2} \int_{-\infty}^{\infty} \sin \varphi e^{-u} d\varphi \quad (5.11)$$

$$\epsilon_{zz} = 1 + \frac{\omega_p^2}{\omega_c^2} \int_{-\infty}^{\infty} \varphi e^{-u} d\varphi \quad (5.12)$$

$$\epsilon_{yx} = -\epsilon_{xy} = \frac{\omega_p^2}{\omega_c^2} \int_{-\infty}^{\infty} (1 - \cos \varphi) e^{-u} d\varphi \quad (5.13)$$

where

$$\begin{aligned} u &= \frac{i\omega_p}{\omega_c} - \frac{v^2}{2\omega_c^2} (\vec{k} \cdot \vec{L})^2 \\ &= \frac{i\omega_p}{\omega_c} + \frac{k^2 v^2}{2\omega_c^2} \varphi^2 + \frac{k^2 v^2}{\omega_c^2} (1 - \cos \varphi), \end{aligned}$$

k_\perp and k_\parallel are the wave numbers perpendicular and parallel to the magnetic field respectively. In Appendix D we show how to express Eqs. (5.11) to (5.13) in terms of the Hilbert transform of the gaussian as defined by Fried and Conte.¹² The result is

$$\epsilon_{xx} = \epsilon_{yy} = 1 + \frac{\omega_p^2}{\omega c} \exp\left[-\frac{\lambda^2}{2}\right] \sum_{-\infty}^{\infty} I_n (z_{n+1} - z_{n-1}) \quad (5.14)$$

$$\epsilon_{zz} = 1 - \frac{\omega_p^2}{\omega c} \zeta_n^2 \exp\left[-\frac{\lambda^2}{2}\right] \sum_{-\infty}^{\infty} I_n z_n \quad (5.15)$$

$$\epsilon_{xy} = -\epsilon_{yx} = -\frac{i\omega_p^2 \zeta_n^2}{\omega c} \exp\left[-\frac{\lambda^2}{2}\right] \sum I_n \left(z_n - \frac{z_{n+1} + z_{n-1}}{2} \right) \quad (5.16)$$

where $I_n = I_n(\lambda^2/2)$ are modified Bessel functions,

$$\zeta_n = \frac{\omega - i\omega_c}{\sqrt{2} k_\parallel v_\theta},$$

$$\lambda = \frac{\sqrt{2} k_\parallel v_\theta}{\omega_c},$$

and $Z_n = Z(\zeta_n)$ is the Hilbert transform of the gaussian, commonly called the Fried function, defined by

$$Z(\zeta_n) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} \frac{e^{-x^2}}{x - \zeta_n} dx \quad \text{Im}(\zeta_n) > 0. \quad (5.17)$$

Properties of this function are discussed in References 3 and 4, and a few simple relations involving $Z(\zeta)$ are given in Appendix D.

The dielectric tensor described by Eqs. (5.11) to (5.16) is much simpler than the "dielectric" tensor derived by earlier authors and described in the book by Stix.¹³ In the representation given by Stix, the plasma conduction current is not divided into magnetization and polarization currents and hence the "dielectric" tensor is not truly the tensor

which relates the electric field to the displacement field. Even under quasi-static approximation, our results do not agree with that given by Stix.

B. THE DIELECTRIC TENSOR IN PLASMAS WITH TEMPERATURE ANISOTROPY

The derivation of the dielectric tensors for plasmas with temperature anisotropy is given in Appendix C. Equations (5.14), (5.15), and (5.16) remain unchanged, but some of the variables must be redefined as follows

$$\lambda^2 = \frac{2k_{\perp}^2 v_{\theta\perp}^2}{\omega_c^2}$$

and

$$\epsilon_n = \frac{\omega - n\omega_c}{\sqrt{2} k_{\parallel} v_{\theta\parallel}}$$

where

$$v_{\theta\parallel} = \frac{kT}{m}$$

and

$$v_{\theta\perp}^2 = \frac{kT}{m}$$

The limiting case of interest is $v_{\theta\perp} = 0$. In this limit the dielectric tensor elements become

$$\epsilon_{xx} = \epsilon_{yy} = 1 + \frac{\omega_p^2}{2\sqrt{2}\omega_c k_{\parallel} v_{\theta\parallel}} \left[Z\left(\frac{\omega-\omega_c}{\sqrt{2} k_{\parallel} v_{\theta\parallel}}\right) - Z\left(\frac{\omega+\omega_c}{\sqrt{2} k_{\parallel} v_{\theta\parallel}}\right) \right] \quad (5.18)$$

$$\epsilon_{zz} = 1 - \frac{\omega_p^2}{2k_{\parallel}^2 v_{\theta\parallel}^2} Z\left(\frac{\omega}{\sqrt{2} k_{\parallel} v_{\theta\parallel}}\right) \quad (5.19)$$

and

$$\epsilon_{xy} = -\epsilon_{yx} = \frac{-i\omega_p^2}{2\sqrt{2}\omega_c k_{\parallel} v_{\theta\parallel}} \left[2Z\left(\frac{\omega}{\sqrt{2} k_{\parallel} v_{\theta\parallel}}\right) - Z\left(\frac{\omega-\omega_c}{\sqrt{2} k_{\parallel} v_{\theta\parallel}}\right) - Z\left(\frac{\omega+\omega_c}{\sqrt{2} k_{\parallel} v_{\theta\parallel}}\right) \right]. \quad (5.20)$$

These agree with the results obtained by Lichtenberg and Jayson.⁹ Lichtenberg and Jayson derived the tensor by assuming that the plasma consisted of a continuum of streaming electrons with a gaussian velocity distribution along the magnetic field. They obtained the polarization tensor by integrating over the contribution from the continuum of electron streams. In Chapter VI the dispersion relation for the Lichtenberg-Jayson model is compared with that of a fully thermal plasma model.

The cold plasma dielectric tensor is recovered by letting $v_{\theta \parallel}$ approach zero in Eqs. (5.18) to (5.20).

C. DIELECTRIC TENSOR FOR A MULTI-COMPONENT PLASMA

The polarization vector for a multi-component plasma is given by the sum of the polarization in each of the components. Thus, the dielectric tensor is given by

$$\vec{\epsilon} = I + \sum_j \vec{\pi}_j$$

where $\vec{\pi}_j$ is the electric susceptibility tensor for the j^{th} species. The elements of $\vec{\pi}_j$ are given by

$$\pi_{zzj} = -\frac{\omega_p^2}{\omega_c^2} \zeta_{oj}^2 \exp\left[-\frac{\lambda_j^2}{2}\right] \sum_{-\infty}^{\infty} I_n z'_n \quad (5.21)$$

$$\pi_{xyj} = -\pi_{yxj} = -\frac{i\omega_p^2 \zeta_{oj}}{\omega_c^2 \omega} \exp\left[-\frac{\lambda_j^2}{2}\right] \sum_{-\infty}^{\infty} I_n \left(z_n - \frac{z_{n+1} + z_{n-1}}{2}\right) \quad (5.22)$$

and

$$\pi_{xxj} = \pi_{yyj} = \frac{\omega_p^2 \zeta_{oj}}{2\omega_c^2 \omega} \exp\left[-\frac{\lambda_j^2}{2}\right] \sum_{-\infty}^{\infty} I_n (z_{n+1} - z_{n-1}) \quad (5.23)$$

where

$$I_n = I_n \left(\frac{\lambda_j^2}{2} \right) ,$$

$$z_n = z(\zeta_{nj}) ,$$

$$\zeta_{nj} = \frac{\omega - n\omega_{cj}}{\sqrt{2} k_{\parallel} v_{\theta j}} ,$$

$$\lambda_j = \frac{\sqrt{2} k_{\perp} v_{\theta j}}{\omega_{cj}} .$$

D. THE QUASI-STATIC DISPERSION RELATION FOR THE INFINITE PLASMA

Having obtained the dielectric tensors, we can now derive the dispersion relation for the plane electrostatic waves in the magnetoplasma. The distinguishing feature of electrostatic waves is that the electric field is derivable from a scalar potential

$$\vec{E}_1(\vec{x}, t) = -\nabla \phi(\vec{x}, t) , \quad (5.24)$$

and, hence,

$$\nabla \times \vec{E}_1(\vec{x}, t) = 0 .$$

This approximation, commonly called the quasi-static approximation, is valid whenever the phase velocities of the waves are much less than the speed of light. Using this analysis and assuming plane wave propagation of the form $\exp[i\omega t - i\vec{k} \cdot \vec{x}]$, we obtain the following result, relating the potential and the electric field.

$$\vec{E}[\omega, \vec{k}] = i\vec{k} \phi[\omega, \vec{k}] . \quad (5.25)$$

From the second Maxwell equation we get

$$\begin{aligned}
 \nabla \cdot \vec{D}(t, \vec{x}) &= -ik \cdot \vec{E}_{\perp, k} \exp(ikc - ik \cdot \vec{x}) \\
 &= -ik \cdot \vec{e} \cdot \vec{E}_{\perp, k} \exp(ikc - ik \cdot \vec{x}) \\
 &= 0
 \end{aligned} \tag{5.26}$$

Direct substitution of Eq. (5.25) into Eq. (5.24) yields the following relation

$$(\epsilon_{xx} k_x^2 + \epsilon_{yy} k_y^2 + \epsilon_{zz} k_z^2) \delta(k_x, k_y, k_z, \omega) = 0 \tag{5.27}$$

which in turn yields the dispersion relation

$$\epsilon_{xx} k_x^2 + \epsilon_{yy} k_y^2 = 0 \tag{5.28}$$

where $k_{\perp}^2 = k_x^2 + k_y^2$ is the square of the wave number perpendicular to the magnetic field. As expected, the dispersion relation is independent of the angle between the perpendicular component of \vec{k} and the x axis. This dispersion relation, though it appears to be different, is identical to the result obtained by Stix.¹¹

In an electron plasma the dispersion relation can be given in terms of one integral or one series as follows

$$k_x^2 + k_y^2 + \left(\frac{eP}{mc}\right)^2 \left[1 - \frac{\omega}{c} S_1\right] = 0 \tag{5.29}$$

where

$$\begin{aligned}
 S_1 &= \int_0^\infty \exp\left[-\frac{\omega}{c} t - \frac{k_x^2 r_0^2}{2\varepsilon c} t^2 - \frac{k_x^2}{2} (1 - \cos t)\right] dt \\
 &= \exp\left[-\frac{k_x^2}{2}\right] \sum_{n=0}^{\infty} \frac{\frac{\omega}{c}}{\sqrt{\varepsilon k_x r_0}} I_n Z_n
 \end{aligned}$$

and I_n , I_n and Z_n are as defined in Section V A.

The special case of purely perpendicular propagation ($k_z = 0$) has been studied by Bernstein.⁴⁶ For this case we have from Eq. (5.28)

$$\epsilon_{xx} = 0 \quad (5.30)$$

as the dispersion relation. By using Eq. (5.29) and the asymptotic relation for I_n given in Appendix D, we obtain the following dispersion relation for the "Bernstein" modes.

$$1 - \frac{2\omega^2}{\omega_c^2} \exp\left[-\frac{\omega^2}{\omega_c^2}\right] \underset{n \rightarrow \infty}{\sim} \frac{n! \left(\omega^2/2\right)}{\omega^2 - \omega_c^2} = 0. \quad (5.31)$$

This dispersion predicts resonances near the harmonics of the cyclotron frequency. Several papers on the experimental observations of such resonances have been published.^{47, 48} A novel method of summing the series of Eq. (5.31) in terms of Watson's cylinder function has been given by Durfler.⁴⁹ A computer program based on this result is used in obtaining the electric susceptibility tensor for the ions.

B. CYLINDRICAL WAVES

In this section we illustrate a method of synthesizing cylindrical waves from the plane waves. The rf potential for a plane wave may be expressed as follows

$$\delta(\omega, \vec{k}) = \delta(\omega, \vec{k}) e^{-i\vec{k} \cdot \vec{x}}. \quad (5.32)$$

From the potential the electric field and the displacement vectors can be obtained

$$\vec{E}(\omega, \vec{k}) = -\nabla \delta(\omega, \vec{k}) = i\vec{k} \delta(\omega, \vec{k}) e^{-i\vec{k} \cdot \vec{x}} \quad (5.33)$$

$$\vec{D}(\omega, \vec{k}) = i\overline{\epsilon} \cdot \vec{k} \delta(\omega, \vec{k}) e^{-i\vec{k} \cdot \vec{x}}. \quad (5.34)$$

In the cylindrical coordinate system we let

$$k_x = k_{\perp} \cos \varphi$$

$$k_y = k_{\perp} \sin \varphi$$

$$x = r \cos \theta$$

$$y = r \sin \theta$$

where φ is the angle between the z axis and the plane containing the z axis and \vec{k} . The potential can now be expressed in the following manner

$$\emptyset[\omega, r, \theta, z] = \emptyset[\omega, k_{\perp}, k_{\parallel}, \varphi] \exp[-ik_{\parallel} z - ik_{\perp} r \cos(\theta - \varphi)] . \quad (5.35)$$

The cylindrical wave is synthesized by taking these waves with identical amplitude, k_{\perp} and k_{\parallel} but with phase variation of the form

$$\emptyset[\omega, k_{\perp}, k_{\parallel}, \varphi] = \frac{\emptyset_0}{2\pi} e^{im\varphi}$$

where m is an integer. Synthesis of such plane waves yields ⁵⁰

$$\begin{aligned} \emptyset[\omega, r, \theta, z] &= \frac{\emptyset_0}{2\pi} \int_{-\pi}^{\theta+\pi} e^{im\varphi} \exp[-ik_{\parallel} z - ik_{\perp} r \cos(\theta - \varphi)] d\varphi \\ &= \emptyset_0 e^{im\theta} e^{-ik_{\parallel} z} J_m(k_{\perp} r) \end{aligned} \quad (5.36)$$

where $J_m(k_{\perp} r)$ is the Bessel function of the order m . Similar integrations for the electric and displacement fields yield

$$E_z[\omega, r, \theta, z] = -ik_{\parallel} \emptyset_0 \exp[im\theta - ik_{\parallel} z] J_m(k_{\perp} r) \quad (5.37)$$

$$E_{\theta}[\omega, r, \theta, z] = \emptyset_0 \frac{im}{r} \exp[im\theta - ik_{\parallel} z] J_m(k_{\perp} r) \quad (5.38)$$

$$E_r[\omega, r, \theta, z] = k_{\perp} \emptyset_0 \exp[im\theta - ik_{\parallel} z] J'_m(k_{\perp} r) \quad (5.39)$$

$$D_z[\omega, r, \theta, z] = -i\epsilon_{zz} k_z \emptyset_0 \exp[i m \theta - ik_z z] J_m(k_\perp r) \quad (5.40)$$

$$D_r[\omega, r, \theta, z] = \emptyset_0 \exp[i m \theta - ik_z z] \left[\frac{im \epsilon_{xy}}{r} J_m(k_\perp r) + k_\perp \epsilon_{xx} J'_m(k_\perp r) \right] \quad (5.41)$$

$$D_\theta[\omega, r, \theta, z] = \emptyset_0 \exp[i m \theta - ik_z z] \left[\frac{im \epsilon_{xx}}{r} J_m(k_\perp r) - k_\perp \epsilon_{xy} J'_m(k_\perp r) \right]. \quad (5.42)$$

This technique of cylindrical wave synthesis has been employed by others in the past. In our representation ϵ is independent of φ , the integration variable. In Stix' representation the dielectric tensor is a function of φ , and the integrals for the displacement vector is somewhat more difficult to evaluate than in our case.

The solution obtained above is valid for an infinite plasma. Our ultimate goal is to find the solution for a finite plasma, particularly a cylindrical column of plasma. In a finite plasma the most difficult task is the treatment of the boundary. To make the problem manageable, we must assume that the plasma column is uniform with a sharp boundary. In reality, a sharp boundary cannot occur because of thermal motion, though such a model may approximate the plasma column, as suggested by the theory and, in particular, the measurements discussed in Chapter IV. In Chapter VI we shall use the fields given by Eqs. (5.37) to (5.42) as the solution within the cylindrical plasma column and match them to the fields outside the plasma.

VI. ELECTROSTATIC WAVES IN A CYLINDRICAL COLUMN OF MAGNETOPLASMA

In this chapter we investigate the dispersion relation for electrostatic waves propagating along a column of cylindrical, collisionless magnetoplasma. The geometry we consider is that of an infinitely long, uniform, cylindrical plasma enclosed within a cylindrical waveguide as shown in Fig. 1.1. First, the dispersion relation for the electrostatic waves is derived. Some numerical solutions to the dispersion relation for a Maxwellian electron plasma are presented and compared with the dispersion relations based on other plasma models. Our results are also compared with the available experimental dispersion relations. At low magnetic fields, the surface wave is found to be unstable, and the instability character is investigated. The unstable ion surface wave is also studied.

A. QUASI-STATIC DISPERSION RELATION

Since there are two distinct regions within the waveguide, we need two sets of solutions, one valid within the plasma and the other valid in the free space region between the plasma and the conducting wall. For the plasma region we shall use the quasi-static solution, obtained in the previous chapter and given by

$$E_z[\omega, r, \theta, z] = -ik_{\parallel} \emptyset_o \exp[i\omega t - ik_{\parallel} z] J_m(k_{\perp} r) , \quad (5.37)$$

$$E_{\theta}[\omega, r, \theta, z] = \frac{i\omega}{r} \emptyset_o \exp[i\omega t - ik_{\parallel} z] J_m(k_{\perp} r) , \quad (5.38)$$

$$E_r[\omega, r, \theta, z] = k_{\perp} \emptyset_o \exp[i\omega t - ik_{\parallel} z] J'_m(k_{\perp} r) , \quad (5.39)$$

$$D_z[\omega, r, \theta, z] = -ik_{\parallel} \epsilon_{zz} \emptyset_o \exp[i\omega t - ik_{\parallel} z] J_m(k_{\perp} r) , \quad (5.40)$$

$$D_r[\omega, r, \theta, z] = \emptyset_o \exp[i\omega t - ik_{\parallel} z] \left[\frac{i\omega \epsilon_{xy}}{r} J_m(k_{\perp} r) + k_{\perp} \epsilon_{xx} J'_m(k_{\perp} r) \right] , \quad (5.41)$$

$$D_{\theta}[\omega, r, \theta, z] = \emptyset_o \exp[i\omega t - ik_{\parallel} z] \left[\frac{i\omega \epsilon_{xx}}{r} J_m(k_{\perp} r) - k_{\perp} \epsilon_{xy} J'_m(k_{\perp} r) \right] . \quad (5.42)$$

In the free space region, $b < r < a$, the solution to the equation $\nabla^2 \phi = 0$ with the requirement of $\phi(a, \theta, z) = 0$ is given by

$$\phi(r, \theta, z) = A_0 [J_m(ik_{\parallel}r)H_m(ik_{\parallel}a) - J_m(ik_{\parallel}a)H_m(ik_{\parallel}r)]e^{im\theta-ik_{\parallel}z} \quad (6.1)$$

where $J_m(ik_{\parallel}r)$ and $H_m(ik_{\parallel}r)$ are Bessel and Hankel functions of order m . The components of the electric field are then obtained from Eq. (6.1) by $\bar{E} = -\nabla\phi$. At the free space plasma boundary, the tangential component of the electric field and the normal component of the displacement vector are matched. This yields the following dispersion relation for the waves

$$k_{\perp}^2 \epsilon_{xx} \frac{J'_m(k_{\parallel}b)}{J_m(k_{\parallel}b)} + im\epsilon_{xy} = \frac{ik_{\parallel}b[J'_m(ik_{\parallel}b)H_m(ik_{\parallel}a) - J_m(ik_{\parallel}a)H'_m(ik_{\parallel}b)]}{J_m(ik_{\parallel}b)H_m(ik_{\parallel}a) - J_m(ik_{\parallel}a)H'_m(ik_{\parallel}b)} \quad (6.2)$$

with

$$k_{\perp}^2 + k_{\parallel}^2 \frac{\epsilon_{zz}}{\epsilon_{xx}} = 0$$

and the dielectric tensor elements are as described in Chapter VC. The dispersion relation of Eq. (6.2), in appearance, is very familiar. In the cold plasma model⁷ and in the Lichtenberg-Jayson ($T=0$) model,⁹ the dispersion relation is identical to Eq. (6.2). The only difference, though by no means small, is in the dielectric tensor elements.

To solve the dispersion equation in the form given by Eq. (6.2) is a formidable task. For example, the computation of the dielectric tensors above involves infinite summations of products of the Bessel and Fried functions. Only under certain conditions do these summations converge rapidly enough for computer analysis. In restricting our study to the cylindrically symmetric modes ($m=0$), we have

$$k_{\perp}^2 \epsilon_{xx} \frac{J_1(k_{\parallel}b)}{J_0(k_{\parallel}b)} = \frac{ik_{\parallel}[J_1(ik_{\parallel}b)H_0(ik_{\parallel}a) - J_0(ik_{\parallel}a)H_1(ik_{\parallel}b)]}{[J_0(ik_{\parallel}b)H_0(ik_{\parallel}a) - J_0(ik_{\parallel}a)H_0(ik_{\parallel}b)]}. \quad (6.3)$$

Even for this case, a thorough analysis of all the modes is formidable.

B. THE CASE OF HIGH MAGNETIC FIELD ($\omega_{ce} > \omega_{pe}$) WITH STATIONARY IONS

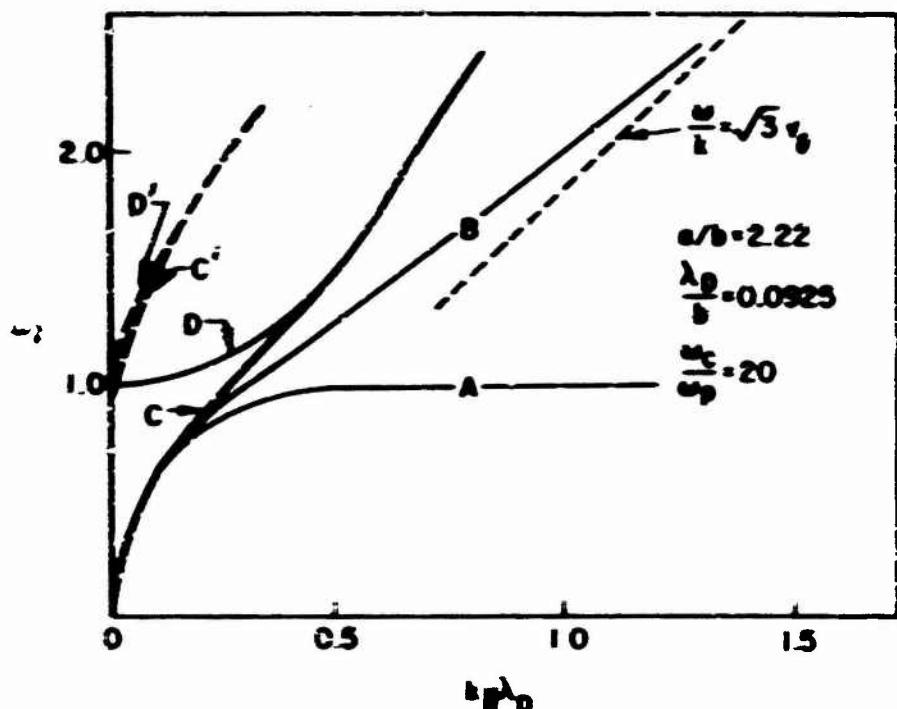

1. Comparison of the Dispersion Relations for Several Different Plasma Models

The dispersion relation for the electrostatic waves in a cold plasma column was first derived by Trivelpiece⁷ and its solutions are commonly called the Trivelpiece modes. The hydrodynamic model, obtained by taking the moments of the Boltzmann equation, was used by Agdur and Weissglas⁸ to study the temperature effects on the Trivelpiece modes. Unfortunately, the hydrodynamic model does not account properly for the temperature effects. In this section we present the dispersion relation for waves in a Maxwellian plasma column and compare it with the dispersion relations derived by using other models. We shall assume that the ions are infinitely heavy.

Equation (6.3) is solved numerically for the Maxwellian electron plasma by assuming real ω and seeking complex k . The computation procedure is described in Appendix E. The result for the lowest order mode is shown in Fig. 6.1. Also shown on the same graph are the dispersion relations for waves in a cold plasma column, in a "hydrodynamic" plasma, and in an infinite Maxwellian plasma. For the infinite hot plasma, the dispersion relation presented is the lowest order Landau mode as defined by Simonen.⁴²

At low values of ω , the three models yield identical dispersion relations, but, at high values of ω , the dispersion relation for the Maxwellian plasma column merges smoothly into the hot infinite plasma dispersion relation, while the dispersion relation for the hydrodynamic model approaches the thermal speed of the one dimensional adiabatic Bohm and Gross⁵¹ waves. As we can see, the wave in the column of the Maxwellian plasma is Landau damped.

The dispersion relation for the zero transverse temperature model ($T_1 = 0$) was also computed, but, at the high magnetic field considered above, the results for $T_1 = 0$ and $T_1 = T_{\parallel}$ are identical. This is not surprising since, at high magnetic fields, the transverse motion of the electrons is inhibited.

FIG. 3.1. DISPERSION RELATIONS FOR VARIOUS PLASMA MODELS.

2. Comparison with Available Experimental Observations

Using the model with $T = 0$, we also compute dispersion curves, which can be compared with the experimental observations of Halmberg and Wharton.¹² Halmberg and Wharton measured the propagation constant and the damping rate at frequencies near the electron plasma frequency.

Their experiment was conducted in a duoplasmatron type hydrogen arc source, which produced a plasma with high longitudinal temperature. Because of the high longitudinal temperature, the model with $T_1 = 0$ is well-suited for the analysis. The experimental density profile given by Malmberg and Wharton is highly nonuniform as shown in Fig. 6.2. For computational purposes the plasma is approximated by a uniform, cylindrical plasma column as shown in curves A and B in Fig. 6.2. For the uniform column, the density is assumed to be $1.6 \times 10^8 / \text{cm}^3$, which matches the asymptotic behavior of the theoretical result to that of the experimental curve. The radius for column A is chosen so that the total number of electrons in the column equals the total number in the nonuniform plasma. Since Malmberg and Wharton report that the absolute value of

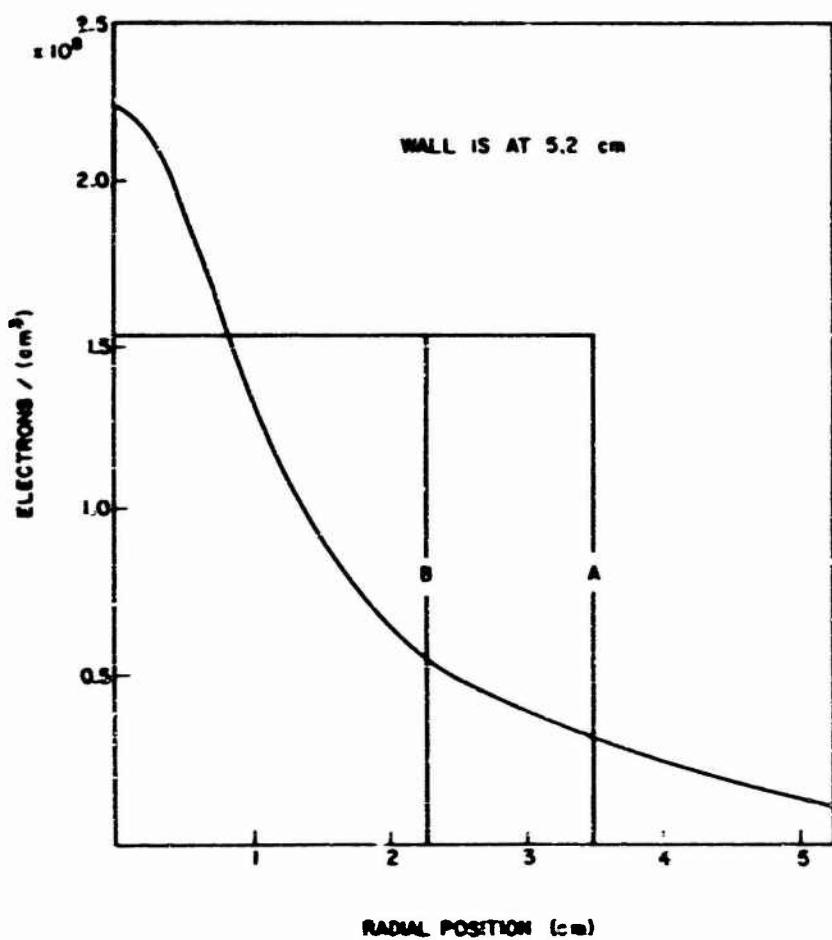

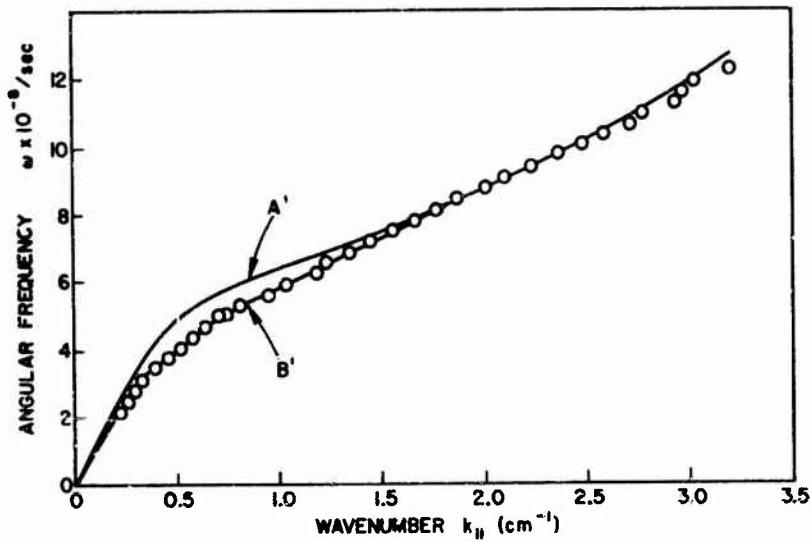

FIG. 6.2. DENSITY PROFILE FOR MALMBERG AND WHARTON EXPERIMENT.

the density profile may not be accurate, the procedure used to obtain the equivalent radius may not be valid. In fact, better agreement with the experimental dispersion relation is obtained when the column is assumed to be 2.25 cm in radius as shown in curve B. From the data supplied by Malmberg and Wharton, we find $\lambda_D = 0.19$ cm and $\omega_c/\omega_p = 4.0$. The real part of k_{\parallel} obtained via the dispersion relation is compared with the experimental result in Fig. 6.3. The curves marked A' and B' are

A' = plasma radius $b = 3.5$ cm

B' = plasma radius $b = 2.25$ cm

FIG. 6.3. ANGULAR FREQUENCY VERSUS WAVE NUMBER.
Experimental data obtained by Malmberg and Wharton is compared with theoretical results.

the theoretical results for plasmas represented by curves A and B of Fig. 6.2. In Fig. 6.4 we have a graph of $\text{Im}(k_{\parallel})/\text{Re}(k_{\parallel})$ versus v_p/v_{θ} , where $v_p = \omega/\text{Re}(k_{\parallel})$ is the phase velocity. The theoretical curve is computed by using B of Fig. 6.2. The agreement between the theory and experimental points is good, despite the approximate nature of the model.

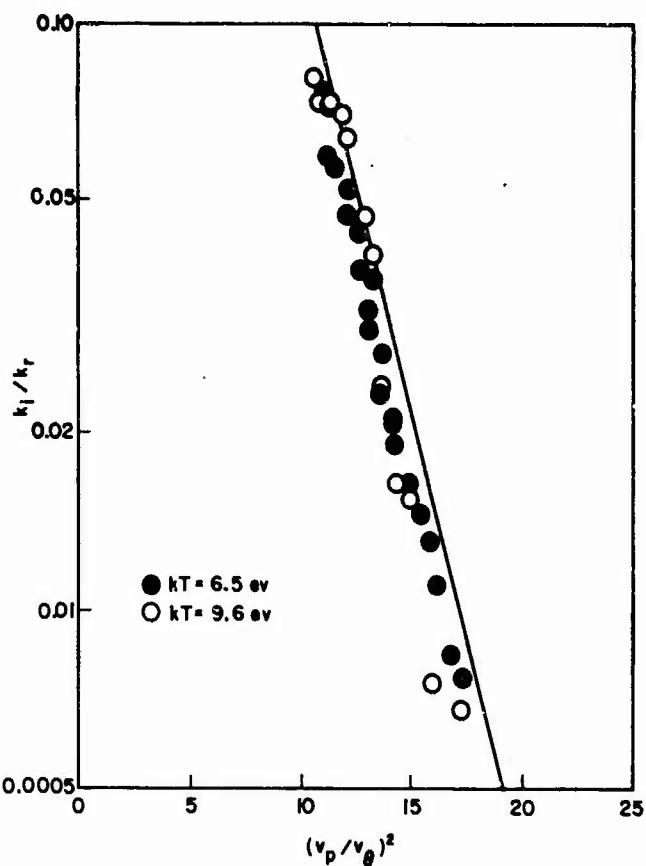

FIG. 6.4. k_i/k_r VERSUS $(v_p/v_\theta)^2$ FOR MALMBERG AND WHARTON EXPERIMENT.

C. SURFACE WAVE INSTABILITY IN ELECTRON PLASMAS AT LOW MAGNETIC FIELDS

When $\omega_c < \omega_p$, the lowest order mode in a cold electron plasma column is a surface wave in the range $\omega_c < \omega < \omega_H$, where $\omega_H = \sqrt{(\omega_p^2 + \omega_c^2)/2}$ (see Fig. 1.2). When the dispersion relation [Eq. (6.2)] was first solved in this region for real ω , instability was indicated. In this section we establish the presence of unstable surface waves and study the character of the instability.

One way to determine the presence of an instability is to map the negative real k_{\parallel} axis into the complex ω plane and see if the roots fall into the lower half plane. Such a mapping for a typical surface mode is shown in Fig. 6.5. Instability is indicated since the roots fall below the real ω axis for a range of $k_{\parallel} b$.

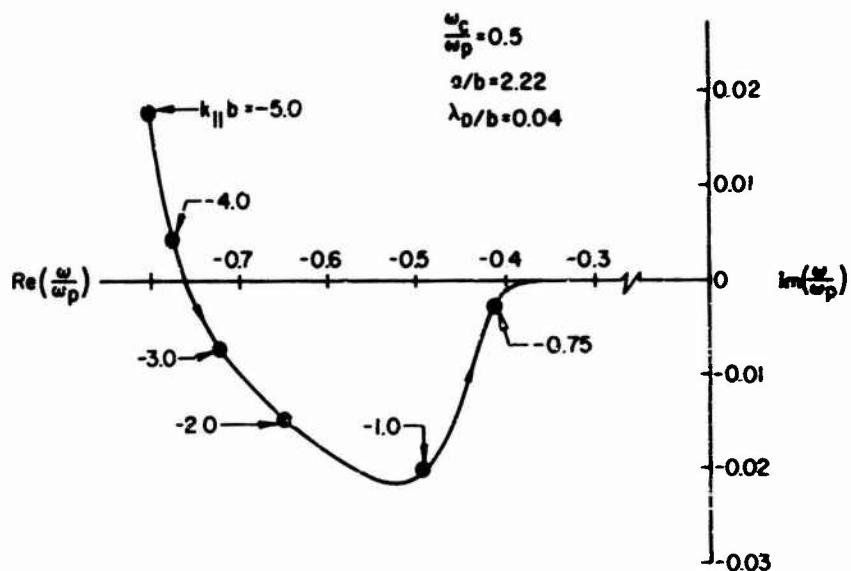

FIG. 65. NEGATIVE REAL $k_{\parallel}b$ AXIS MAPPED INTO THE COMPLEX ω/ω_p PLANE VIA THE DISPERSION RELATION, SHOWING UNSTABLE ROOT.

All instabilities can be classified into two types, convective and nonconvective (absolute) instabilities. A nonconvective instability grows with time until limited by nonlinear effects, while the convective instability is one in which a perturbation is amplified in space. We have established that an instability is present, but, as yet, we have not determined whether it is convective or nonconvective.

Derfler^{14,15} developed two methods of classifying instabilities. The first method is to map the complex ω plane into the complex k_{\parallel} plane through the "positive frequency part" of the dispersion relation and study the saddle-points ($d\omega/dk = 0$), which are caused by the merging of the two roots of the dispersion relation. The way in which the roots merge, as the imaginary part of the frequency is changed, is intimately related to the classification of the instability. Nonconvective instability occurs if and only if the two roots merge across the negative real k_{\parallel} axis with frequencies in the lower half plane. This criterion is more difficult to use than the second one which is described below.

The saddle-points when mapped into the complex ω plane through the dispersion relation become branch points. If the branch point, associated with the instability, falls in the lower half plane, the instability

is macconvective. Otherwise, the instability is convective. Berfler pointed out a method of locating the branch point, and his method is incorporated in Figs. 6.6 and 6.7. First, the negative real τ - ω axis is mapped into the complex ω plane. One then chooses a point A near the most unstable frequency and maps the line AB, i.e., $\text{Re}(\tau) = \text{constant}$, into the frequency plane. This line will bend around the branch point as shown in Fig. 6.7. Now we take a point C on this line and map the line CD of Fig. 6.6 into the frequency plane. These mappings make a nozzle in the complex ω plane. The branch point must be inside the nozzle, and, by repeating the mapping procedure, the nozzle

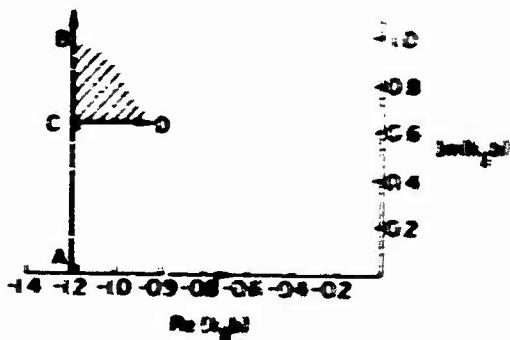

FIG. 6.6. COMPLEX τ - ω PLANE.
The saddle point, $\Im(\tau_k) = 0$,
must be inside the shaded area
(see Fig. 6.7).

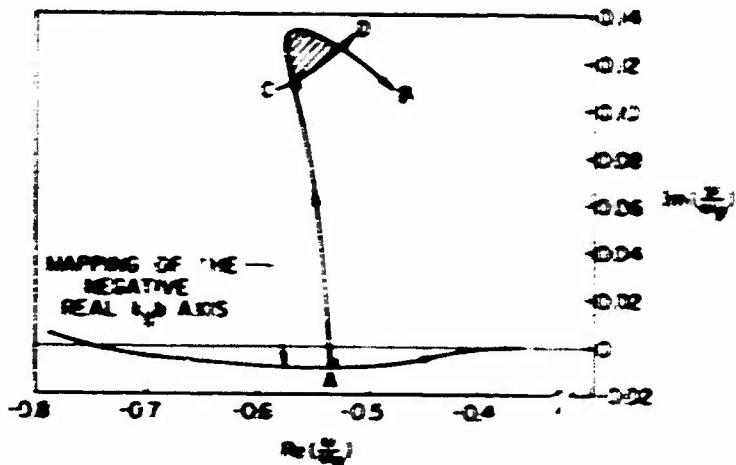

FIG. 6.7. COMPLEX FREQUENCY PLANE. The lines shown in Fig. 6.6 are mapped into complex ω - $\Im(\omega)$ plane via the dispersion relation. The branch point, $\Im(\tau_k) = 0$, must be inside the shaded area.

can be tightened to exactly locate the branch point. In our case, the branch point is in the upper half plane, and, hence, we have a convective instability.

The instability investigated above is a relatively mild case compared to those at lower magnetic fields. Attempts were made to apply the stability criterion at lower magnetic fields, but we were unable to locate the branch point due to computational difficulties. Thus, whether the instability remains convective or not for all values of the magnetic field is still an open question.

We now study the behavior of the instability as a function of the various parameters. Shown in Fig. 5.1 are mappings of the negative real

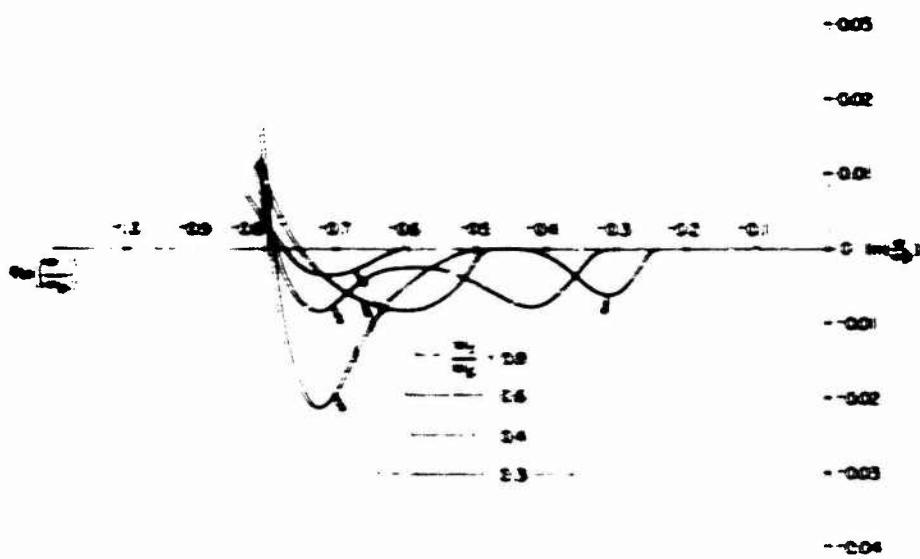

FIG. 5.1. REAL WAVE NUMBERS AS MAPPED INTO THE COMPLEX FREQUENCY PLANE VIA THE DISPERSION RELATION. On the range of parameters shown, the solution represents surface waves. $a/b = 2.22$, $c/b = 0.14$.

wave numbers, k/b , into the complex ω plane for the lowest order mode with ϵ_1/ϵ_2 as a parameter. The instability is strong near the cyclotron frequency and at the hybrid frequency. Also, whenever the cyclotron harmonics are below $\omega = \sqrt{\epsilon_p + \epsilon_c}/2$, the instability is enhanced at these harmonics as seen in Fig. 5.2. At large negative

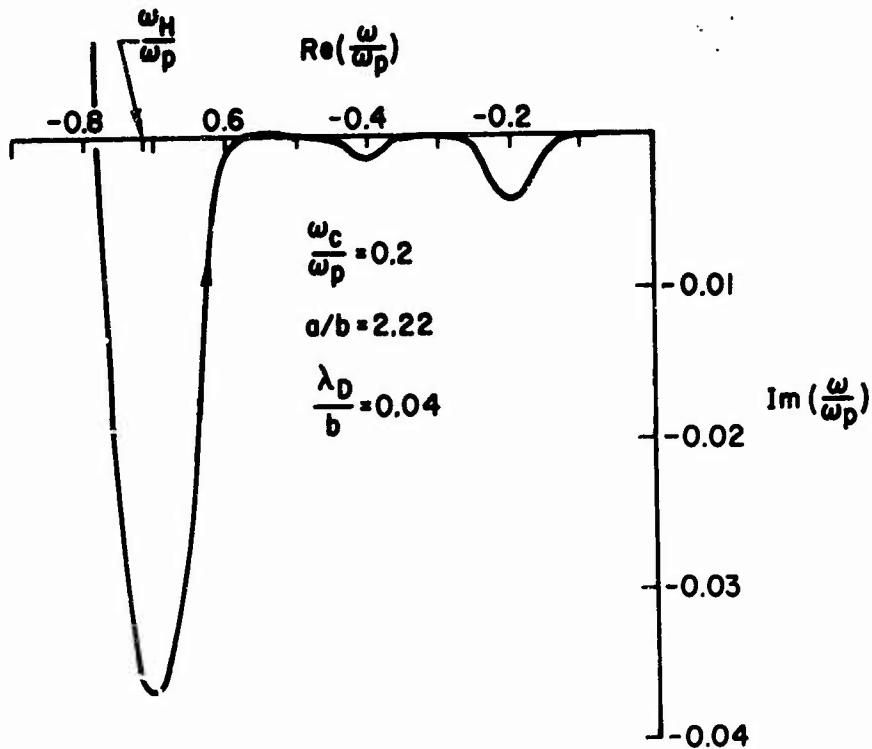

FIG. 6.9. MAPPING OF THE NEGATIVE REAL ($k_{\parallel} b$) AXIS INTO THE COMPLEX ω/ω_p PLANE VIA THE DISPERSION RELATION FOR $\omega_c/\omega_p = 0.2$.

values of $k_{\parallel} b$, Landau damping sets in and makes the waves stable. Shown in Figs. 6.10 and 6.11 are the real and imaginary parts of the frequencies versus $k_{\parallel} b$ with ω_c/ω_p as a parameter. Unlike the surface wave in a cold plasma column for which the dispersion relation goes asymptotically to $\omega = \omega_H$, the real part of ω goes above ω_H as $k_{\parallel} b$ is increased indefinitely. The magnitudes of the electrostatic potential profiles are shown in Fig. 6.12 for $\omega_c/\omega_p = 0.3$. Note that the fields concentrate near the edge of the plasma as the frequency is raised above ω_c .

The curves of Fig. 6.8 seem to indicate that the plasma is more unstable at lower magnetic fields. However, the solution at $\omega_c = 0$ is known to reduce to the cold plasma case and, hence, is stable. Figure 6.13 shows the imaginary part of the most unstable frequency versus ω_c/ω_p . There are two curves, one for the instability at the cyclotron frequency and the other at the hybrid frequency ω_H . The portion of the curve shown by the dotted line was not computed. Although the instability

 ω_c/ω_p .

appear to increase as ω_c is decreased, the solution at $\omega_c = 0$ is known to be stable, and thus a transition curve, such as the one shown by the dotted line, must exist. With cyclotron frequencies below $\omega_c = 0.1 \omega_p$, the summations in the dielectric tensor converge too slowly and accuracy is lost. Consequently, we were unable to cover this range.

The effects of other parameters on the instability are shown in Figs. 6.14 and 6.15. In Fig. 6.14 we show the effect of temperature anisotropy. The roots of the dispersion relation are plotted with T_1/T_{II}

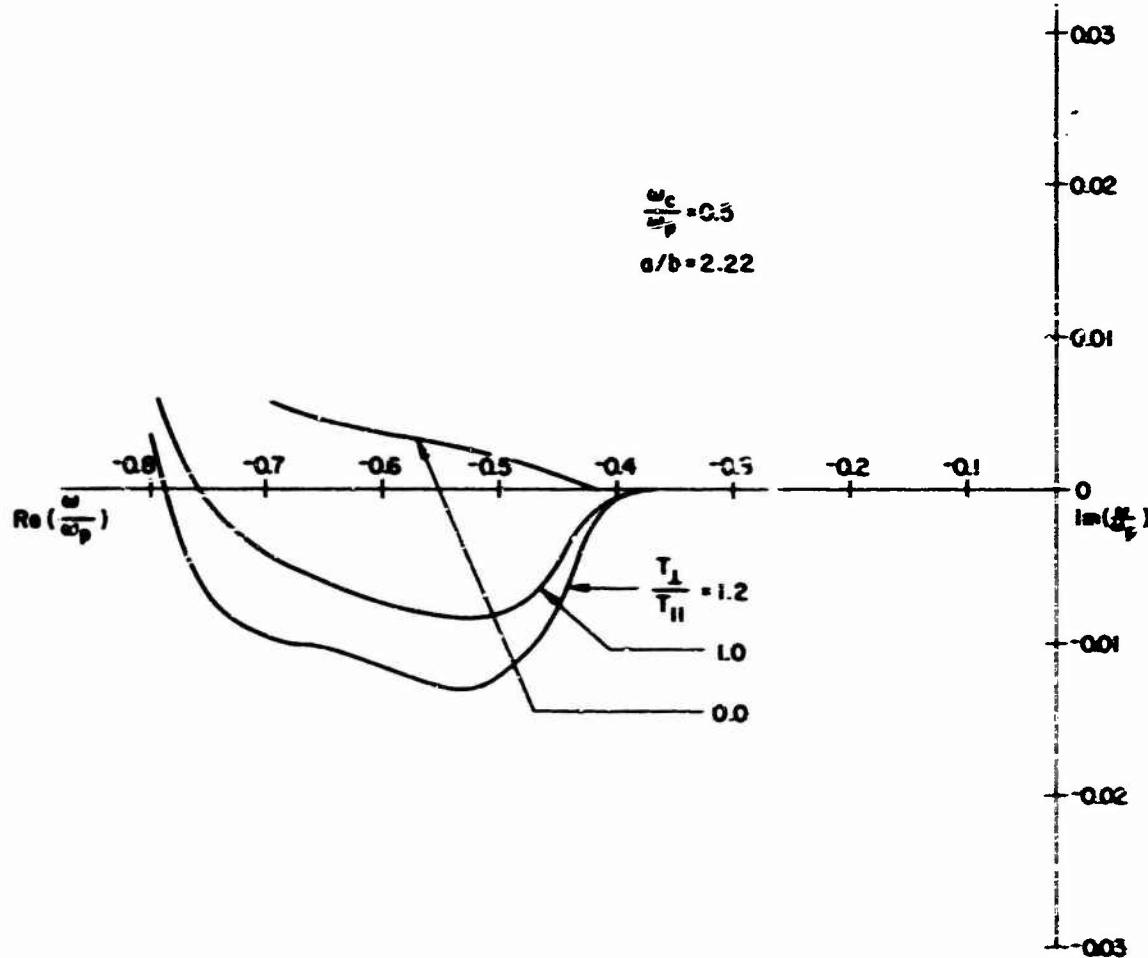

FIG. 6.14. REAL WAVE NUMBER AS MAPPED INTO THE COMPLEX ω/ω_p PLANE VIA THE DISPERSION RELATION. The locus diagram illustrates the effect of the transverse temperature on the surface wave. $\omega_c/\omega_p = 0.5$, $a/b = 2.22$ and $\lambda_D/5 = 0.04$.

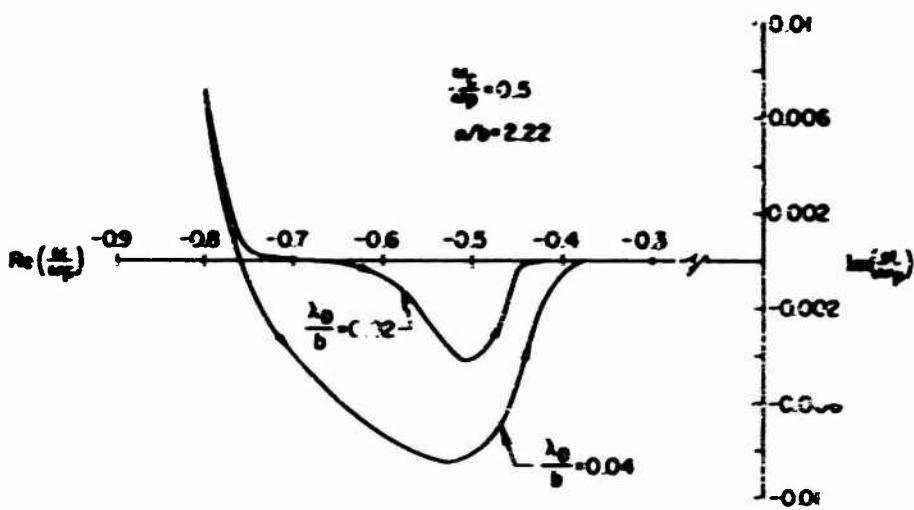

FIG. 6.15. MAPPINGS OF THE NEGATIVE k_b AXIS INTO THE COMPLEX ω/ω_p PLANE WITH λ_D/b AS A PARAMETER.

as a parameter. The plasma is stable when $T = 0$, and the instability, in its nonlinear limit, may provide a mechanism to convert transverse into longitudinal temperature. Shown in Fig. 6.15 are the roots of the dispersion relation with λ_D/b as a parameter. Since we keep ω_p and b constant, a change in λ_D/b is equivalent to a change in the overall temperature. We see that the higher the ratio λ_D/b (hence, higher the temperature), the greater the instability. These graphs indicate that the instability is due to finite Larmor radius effects.

No conclusive experimental evidence of the surface wave instability has been found. There is, however, a report of surface wave self oscillations with zero magnetic field in a plasma column.⁵³ Our theory predicts strong instability at low magnetic field, but the instability should disappear at zero magnetic field. Since we are unable to compute the dispersion relation in the very low magnetic field region, we cannot relate the observed oscillation to our instability. Also at large Larmor radii, our dc model with sharp boundary breaks down.

3. THE COLD PLASMA

In the analysis of parts 2 and 3 we concerned with the electron motion and considered ignored the ion motion. In this section we include the ion motion and investigate the dispersion relations when the ion plasma and the electron dispersion

is a cold plasma consisting of electrons and ions which have equal masses + surface mass is the same.

$$\frac{1}{2} \cdot \frac{1}{m_e} \cdot \frac{1}{m_i} = \frac{1}{m}$$

and $m_e = m_i$. The real and imaginary part of the ion plasma frequency is shown in Fig. 10.1. Since the ion plasma mass is used, the surface mass is equal taken to be negligible. The dispersion law for the plasma with ions and electrons assumed to be equal were difficult than that for the electron plasma. In calculating the dispersion, a calculation approximation was made of 10% error. Further calculations are intended to examine that the resonance frequency of the electrons is zero. Shown in Fig. 10.1 is the result of the dispersion law of the cold plasma. Just like in Fig. 10.1 the real and imaginary

PLASMA.

parts of ω_{ci} versus k_z . The instability appears to be very strong since the ratio of the imaginary part of the frequency to the real part can be of the order of 1/3. We should keep in mind, however, that the model used in this computation is collisionless. In the range of our investigation the longitudinal dielectric tensor element ϵ_{zz} is predominantly electronic. Since the operating frequency is very much lower than the electron plasma frequency, a small number of electro-neutral or electron-ion collisions may alter the result. A further investigation of the ion surface wave instability should, therefore, include the electron-ion collision effects. Also these ion surface waves for practical ion-electron mass ratios have very long wavelengths. Often the wavelengths will exceed the length of the practical plasma column and end effects, such as line tying, may determine whether this instability occurs or not.

2. HIGHER ORDER MODES

Due to the tremendous complexity involved in solving the dispersion relation, very little was done to investigate the higher order modes. The azimuthally varying modes are completely ignored, and some of these modes may be even more unstable than the symmetric mode π_0 We made little attempt to the mode commonly called the upper hybrid mode, which appears in the cold plasma column (see Fig. 1.2). The graph in Fig. 1.10 shows the dispersion relation for the hybrid mode in a hot electron plasma with $\rho_1 = \rho_2$. The mode is naturally complex which may explain the difficulty of the experimenters to observe this mode. In addition to the hybrid mode, there is an infinite number of the hybrid modes in a hot plasma, each associated with one of the Bernstein modes. We did not investigate these modes.

We plan to do underway the study of higher order radial modes, since they are probably just as interesting as the azimuthal modes or direct modes. Our investigation treats only a small portion of a vast problem.

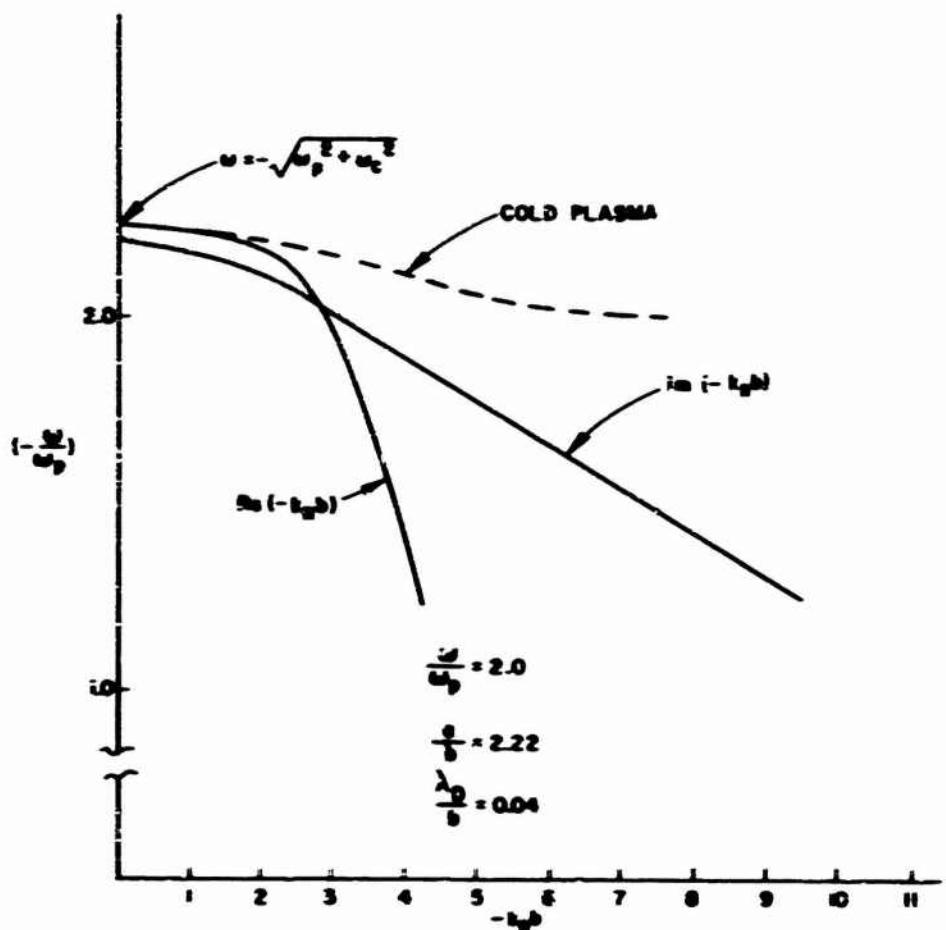

FIG. 6.19. DISPERSION RELATION FOR THE HYBRID MODE.

VII. CONCLUSION

In our study of electrostatic waves we emphasized the effects due to the finite boundary as well as the effects of magnetic fields and plasma temperature. The first part of this report treated plasma diodes in the absence of a magnetic field. A dc study of the equilibrium plasma diode was undertaken to provide a basis for the rf analysis. The dc analysis yielded some interesting results regarding the possibility of plasma formation within a diode. It was found that under equilibrium conditions plasma is formed even when the generation rate of one of the charged species at the walls is orders of magnitude lower than that of the other. The formation of plasma due to the trapping of rare species in the coulomb field of the abundant species was demonstrated in the case of metal emitters where the emission rate of the ions was very much lower than that of the electrons.

An rf analysis using the hydrodynamic model for the nonuniform plasma revealed the existence of a series of electrostatic resonances in the diode. However, an analysis of a uniform plasma diode using a kinetic plasma model showed that the end plate loss, due to absorption of the electrons at the walls, introduces a large loss mechanism. The loss may make some of the resonances predicted from the hydrodynamic model unobservable. Since this loss mechanism is related to the process which causes end plate diffusion in devices such as the Q-machine, the rf measurements of the electrostatic fields may yield information regarding the end plate diffusion coefficient.

The second part of this report dealt with the study of electrostatic wave propagation along a cylindrical column of Maxwellian plasma. First, a dc study of the density profile and azimuthal current in a cylindrical column was conducted. The theoretical analysis of the column under the assumption of complete neutrality showed that at high magnetic fields when the ion Larmor radii became much smaller than the plasma radius, the density drop was confined to the small region at the plasma edge. Experimental measurements indicated that the density drop at the plasma edge is in fact much sharper than that predicted from our theory. For the purpose of rf studies, we assumed that the plasma was uniform with

an infinitely sharp boundary since we were not interested in all types of instabilities, but in surface waves.

To obtain the solution for waves in the hot plasma column, we first derived the dielectric tensor appropriate for plane waves in an infinite plasma. Solutions for waves in a plasma column and the dispersion relation for these waves were obtained through plane wave synthesis. The numerical solution of the dispersion relation revealed that the electrostatic surface waves propagating along the column were unstable.

When only the electrons were assumed to respond to the rf fields, the electron surface waves which occur when $\omega_1 < \omega_2$ were found to be unstable. Since the surface wave became stable when $\omega_1 > \omega_2$, we conclude that the instability was due to finite Larmor radius effects. We were able to classify the instability only in the stability borderline case $\omega_1 = \omega_2$, in which the instability was found to be nonresonant. Such an instability can most likely be suppressed by collisions or by external agents causing ion damping effects. For more generally unstable cases at low magnetic fields, the application of the stability criterion was hampered by numerical difficulties. In fact, it was not possible to compute the dispersion relation in the range $\omega_1 < \omega_2 < \omega_3$ with our program. Our study was also confined to radially-cylindrical symmetric modes.

When the ion motion was included in the analysis, the surface waves which occurs when $\omega_1 < \omega_{pi}$ was also found to be unstable. The unstable ion surface waves are of great interest since the ionization regions is so very strong. Even while the electron surface wave is easily suppressed by raising the cyclotron frequency above the plasma frequency $\omega_1 > \omega_2$, the following condition for the ion surface wave $\omega_1 < \omega_{pi}$ may be difficult to attain in high density plasmas such as those in fusion machines. The numerical analysis was exceedingly difficult for the ion surface waves and we were unable to do a more thorough analysis.

Despite the simplifications made by assuming that the plasma column was infinite with a sharp boundary, the computation of the dispersion relation in the whole was extremely time consuming. A considerable improvement of the computer program is needed before a more exhaustive analysis can be made. A future analysis should include the azimuthally varying waves. Such a study may yield modes which are more unstable than the

cylindrically symmetric modes. A study of azimuthally varying ion waves should prove to be very interesting since many of the observed low frequency instabilities are associated with azimuthally varying waves.¹⁷ A more complete understanding should take into account the nonuniformity of the plasma column. In such a column other instabilities such as the azimuthal instability may occur in addition to the surface wave instability discussed in this paper.

APPENDIX A. LOW DENSITY PROBE MEASUREMENT

In this appendix we show some of the difficulties encountered in probing a low density plasma and the ways in which these problems are overcome. In our sodium plasma the typical density is of the order of $2 \times 10^7/\text{cc}$, which is lower than most of the laboratory plasmas. In the probe measurements of a low density plasma, the smallness of the probe current is the biggest problem. The probe size can be increased to increase the total current, but beyond a certain size the probe disturbs the plasma too much. Also, the probe should be as small as possible to make local measurements.

To obtain accurate probe measurements it is necessary to have the "knee" of the probe curve show clearly. This can be attained by a guard-ring arrangement of the probe. The above consideration is taken into account in the design of the co-axial probe shown in Fig. 4.4. Normally the stem of the guard-ring probe is insulated so that the current is drawn only through the probe surface and the co-planar guard-ring surface. However, since a film of sodium would quickly form on an insulated surface, causing leakage current, we decided not to coat the stem. Instead we made the whole probe as small as possible. The size of the probe is such that the total current drawn to the whole probe at the plasma potential is less than 1 percent of the total electron current from the emitters under normal operating conditions.

Maneuversibility is another desirable feature of a probe. The details of the probe driving mechanism is described by Simenek.⁴² The probe moves in and out as well as rotates so that the probe surface can be made to face either in the azimuthal or axial direction. When an axial magnetic field is applied, the density can be measured by facing the probe in the axial direction, while azimuthal drift can be studied by facing the probe in the azimuthal direction.

Typical probe currents are of the order of a few microamperes. This is a level where leakage currents from various sources begin to interfere with the probe curve, particularly leakage between the guard ring and the probe. Moreover, a dc amplifier is required to amplify the voltage across the current pick-up resistor to drive the XY recorder.

A schematic drawing of the probe circuit is shown in Fig. A.1. The amplifier is a Keithley 604 electrometer amplifier, which has the desired characteristic of high input impedance, low noise and drift. However, it is necessary to keep the electrometer terminals near the ground as shown in Fig. A.1. Since a terminal of the amplifier needs to be grounded, we are forced to use two sweep circuits instead of one to keep the guard ring voltage equal to the probe voltage. The sweep circuit is shown in Fig. A.2. Two such circuits with matched characteristics but insulated from each other were constructed and placed in a metal box. When a master switch is turned on, the two circuits simultaneously sweep out a single identical saw-tooth wave form. The time constant of the sweep is variable from 1 to 4 seconds and the amplitude is variable from 1 to 20 volts.

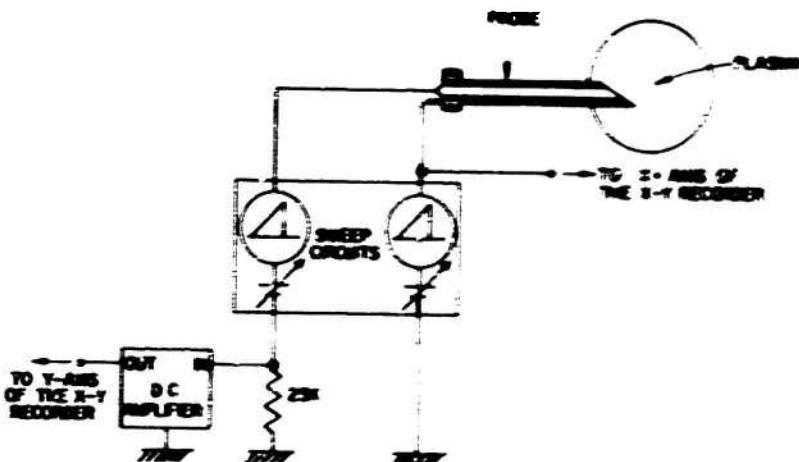

FIG. A.1. PROBE CIRCUIT

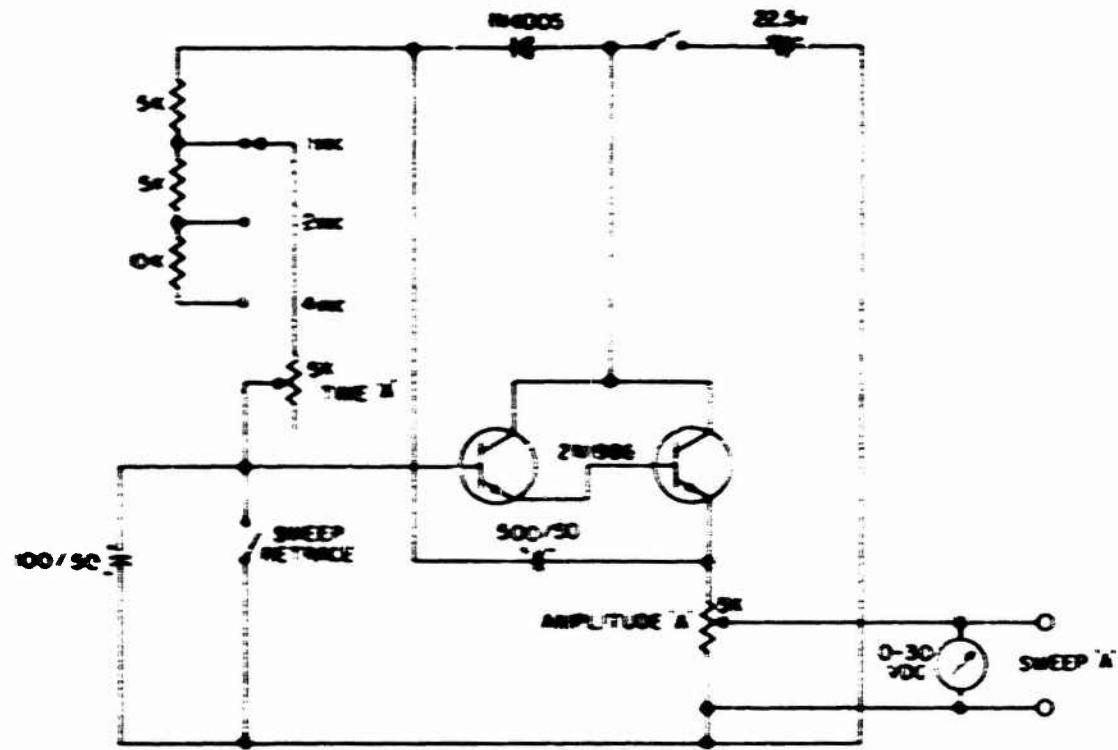

FIG. A.2. SWEEP CIRCUIT.

APPENDIX B. SOLUTION OF THE LINEARIZED BOLTZMANN EQUATION

In this appendix we obtain a solution of the linearized Boltzmann equation for a uniform plasma in a magnetic field. The solution has been derived by others using several different approaches, but we present a derivation here for the sake of completeness. The analysis can be generalized to any species of the plasma, but to avoid extra subscript we shall apply the analysis to electrons only. We shall assume that the plasma is collisionless and that there is no dc electric field. Then the zeroth and the first order Boltzmann equations are given by

$$(\vec{v} \times \vec{B}_0) \cdot \frac{\partial f_0(\vec{v})}{\partial \vec{v}} = 0 \quad (B.1)$$

$$\frac{\partial f_1(t, \vec{x}, \vec{v})}{\partial t} + \vec{v} \cdot \frac{\partial f_1(t, \vec{x}, \vec{v})}{\partial \vec{x}} - \frac{e}{m} (\vec{v} \times \vec{B}_0) \cdot \frac{\partial f_1(t, \vec{x}, \vec{v})}{\partial \vec{v}} = \frac{e}{m} \left(\vec{E}_1(t, \vec{x}) + \vec{v} \times \vec{B}_1(t, \vec{x}) \right) \cdot \frac{\partial f_0(\vec{v})}{\partial \vec{v}}. \quad (B.2)$$

Let us make the following definition

$$\frac{e \vec{B}_0}{m} = \vec{\omega}_c = \vec{n} \omega_c$$

where \vec{n} is a unit vector in the direction of the magnetic field. We Fourier analyze the linearized equation in space ($\text{Im } (\vec{k}) = 0$) and Laplace analyze in time ($\text{Im } (\omega) < 0$ on L.I.P.) to get

$$\begin{aligned} i(\omega - \vec{k} \cdot \vec{v}) f_1[\omega, \vec{k}, \vec{v}] + \omega_c (\vec{n} \times \vec{v}) \cdot \frac{\partial}{\partial \vec{v}} f_1[\omega, \vec{k}, \vec{v}] \\ = \frac{e}{m} \left(\vec{E}[\omega, \vec{k}] + \vec{v} \times \vec{B}[\omega, \vec{k}] \right) \cdot \frac{\partial f_0(\vec{v})}{\partial \vec{v}} + f_1(0, \vec{k}, \vec{v}) \end{aligned} \quad (B.3)$$

where $f_1(0, \vec{k}, \vec{v})$ is the initial value of $f_1(t, \vec{k}, \vec{v})$. Equation (B.3) can be solved by the method of characteristics.⁵⁶ By introducing a parameter t so that $\vec{v} = \vec{v}(t)$, the characteristics of Eq. (B.3) become

$$\dot{\vec{v}} = \omega_c (\vec{n} \times \vec{v}) \quad (B.4)$$

and

$$\dot{f}_1[\omega, \vec{k}, \vec{v}] + i(\omega - \vec{k} \cdot \vec{v}) f_1[\omega, \vec{k}, \vec{v}] = g[\vec{v}] \quad (B.5)$$

where the dot represents the derivative with respect to the parameter t and

$$g[\vec{v}] = \frac{e}{m} \left(\vec{E}[\omega, \vec{k}] + \vec{v} \times \vec{B}[\omega, \vec{k}] \right) \cdot \frac{\partial f}{\partial \vec{v}} + f_1[\omega, \vec{k}, \vec{v}] . \quad (B.6)$$

Note that t is not the "time" which has been taken out of the problem by Laplace analysis. Equation (B.4) is solved by introducing the gyro-tensor defined by

$$\vec{D}(\varphi) = \vec{n} \vec{n} + (I - \vec{n} \vec{n}) \cos \varphi - \vec{n} \times I \sin \varphi \quad (B.7)$$

or, in tensor notation, by

$$D_{ij}(\varphi) = n_i n_j + (\delta_{ij} - n_i n_j) \cos \varphi - \epsilon_{ijk} n_k \sin \varphi . \quad (B.8)$$

Then

$$\vec{v}(t) = \vec{D}(-\omega_c t + \omega_c t') \cdot \vec{v}(t') \quad (B.9)$$

satisfies Eq. (B.4), as can be seen by inspection. The homogeneous part of Eq. (B.5) gives

$$\frac{d \ln f_H}{dt} = -i(\omega - \vec{k} \cdot \vec{v}) . \quad (B.10)$$

Thus

$$\begin{aligned} \ln f_H &= -i\omega t + i \int^t \vec{k} \cdot \vec{v}(t') dt' + \text{constant} \\ \text{or} \quad f_H &= C \exp \left[-i\omega t + i \int^t \vec{k} \cdot \vec{v}(t') dt' \right] \end{aligned} \quad (B.11)$$

where \tilde{C}_2 is given by Eq. 3.9. We solve the differential equation by the method of variation of constants. Differentiating

$$(\tilde{C}_2 \tilde{A}, \tilde{B}) + C_2 = \tilde{C}_2'$$

from Eq. 3.5 we obtain

$$\tilde{C}_2' + \tilde{C}_2'' + \dots - \tilde{B}^2 \tilde{C}_2 + \tilde{C}_2''' = 0. \quad 3.11$$

From Eq. 3.10 we get

$$\tilde{C}_2' + \tilde{C}_2'' - \tilde{B}^2 \tilde{C}_2 + \dots = 0.$$

Therefore,

$$\tilde{C}_2 = C_2^{\frac{1}{2}} \quad 3.12$$

Solving for $C_2^{\frac{1}{2}}$ we have

$$C_2^{\frac{1}{2}} = \int \frac{dx}{\sqrt{f_2(x)}}. \quad 3.13$$

Thus,

$$C_2(\tilde{A}, \tilde{B}) = \text{constant} \cdot f_2^{-\frac{1}{2}} = \int \frac{dx}{\sqrt{f_2(x)}} \text{constant} = 0 \quad 3.14$$

or

$$\begin{aligned} C_2(\tilde{A}, \tilde{B}, \tilde{C}) &= C_2(\tilde{A}, \tilde{B}) C_2 \left[-\omega^2 x - \int \tilde{B}^2 dx + \right. \\ &\quad \left. - \int \omega^2 \left[-\omega^2 x - \int \tilde{B}^2 dx \right] d\tilde{B} \right] = 0 \end{aligned} \quad 3.15$$

$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty}$

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty}$$

$$= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty}$$

$$= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty}$$

$$= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty}$$

Let us change the variables of integration so that $x_1 = \theta_1$, $x_2 = \theta_2$, $x_3 = \theta_3$, $x_4 = \theta_4$, $x_5 = \theta_5$, $x_6 = \theta_6$, $x_7 = \theta_7$, $x_8 = \theta_8$, $x_9 = \theta_9$, $x_{10} = \theta_{10}$. Then the Jacobian is unity. Thus, it is clear that the integral is equal to the volume of the unit hypercube.

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty}$$

The parameter θ is now called the set of latent variables.

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty}$$

By changing the integration variable to $\theta_1, \theta_2, \dots, \theta_{10}$ and arranging the terms,

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty}$$

one obtains precisely the equation of the Bayes rule for the case

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty}$$

Now for the solution we take the initial condition at $t = 0$. Now
we have to set independent variables at the origin since under the
homogeneous problem, we find that the solution is in the form of
certain terms in series. Then from Eq. 1.1 we get

$$x_1^2 + \frac{1}{2}x_1^2 + \frac{1}{2}x_1^2 - \frac{x_1^2}{2} = 0.2$$

It is the same to say the value of x_1^2 is 0.2. Then the
value of x_1^2 and solution is 0.2. Now we get

$$x_1^2 + x_2^2 + x_3^2 + x_4^2 = 0.2$$

Now we can see the values of x_1^2 and x_2^2 are approximately 0.1.
So x_3^2 and x_4^2 must be zero. Then

$$x_1^2 + x_2^2 + x_3^2 + x_4^2 = 0.2$$

It is the same to say the value of x_1^2 .

$$x_1^2 = 0.2$$

$$x_2^2 = 0.2$$

$$x_1^2 + x_2^2 + x_3^2 + x_4^2 = 0.2$$

Now taking the derivative of x_1^2 we have

$$\dot{x}_1^2 = \frac{\partial^2}{\partial t^2} + \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} + \frac{\partial^2}{\partial x_3^2}$$

$$+ \frac{\partial^2}{\partial x_4^2} = 0.2$$

0.2

$$25 \cdot 2 \cdot 2 \cdot \frac{2}{n} + 2 \cdot 2 \cdot \frac{2}{n}$$

3.3

$$2 \cdot 2 \cdot 2$$

Therefore

$$25 \cdot 2 \cdot 2 \cdot \left(2 \cdot \frac{2}{n} + 2 \cdot \frac{2}{n} \right) \\ + 2 \cdot 2 \cdot \frac{2}{n}$$

3.3

Now we can see if $\int_0^2 f(x) dx = 3.3$ or not.

$$25 \cdot 2 \cdot 2 \cdot 2 \cdot \frac{2}{n} + 2 \cdot 2 \cdot \frac{2}{n} = 3 \cdot \frac{2 \cdot 2}{n} = 3.3$$

Therefore

$$25 \cdot 2 \cdot 2 \cdot \frac{2}{n} \int_0^2 f(x) dx = 3 \cdot \frac{2 \cdot 2}{n} \int_0^2 f(x) dx$$

$$\int_0^2 f(x) dx = \frac{3 \cdot \frac{2 \cdot 2}{n}}{25 \cdot 2 \cdot 2}$$

APPENDIX C. POLARIZATION AND MAGNETIZATION CURRENTS

The force exerted on the charge density in a hot electron plasma can be described from the relation

$$\vec{F} = -e \vec{E} + q \vec{B} \times \vec{J}$$

(C.1)

$$\vec{F} = -e \vec{E} + q \vec{B} \times \vec{J}$$

(C.2)

where $\vec{F}_{\text{ext}} = e \vec{E}$ is the electric field, \vec{B} is the magnetic field, \vec{J} is the current density in the plasma current, $q = e$ is the electron and ion charge, and

$$\vec{F} = -e \vec{E} + q \vec{B} \times \vec{J}$$

(C.3)

so that the plasma can be magnetized magnetized by the polarization and the magnetization is without distinguishing free charges and free ion terms. To complete the analysis we derive a few useful tensor relationships of interest. If we equate the plasma current with the two terms for the case of an isotropic sheet under uniform electromagnetic polarization, a result will be the electrostatic polarization function as given in Section 2.

Current Relations

We shall start out with a few general tensor relations. Let \vec{E}, \vec{B} and \vec{J} be arbitrary vectors. Then we have

$$\vec{E} \cdot \vec{E} = \vec{B} \cdot \vec{B} = \vec{J} \cdot \vec{J} = \vec{E}^2 = \vec{B}^2 = \vec{J}^2 = 0$$

Let \vec{E} be an arbitrary vector. Then $\vec{E} \cdot \vec{B} = 0$ is a vector and from Eq. (C.1) we have

$$\vec{E} \cdot \vec{B} + \vec{J} \cdot \vec{B} = \vec{J} \cdot \vec{B} = 0$$

(C.4)

By writing the reflected waves, we obtain

$$\bar{I} \cdot \bar{S} \cdot \bar{E} \cdot \bar{S} \cdot \bar{I} \cdot \bar{E} \cdot \bar{S}.$$

(2.2)

Since \bar{I} is arbitrary, we let $\bar{I} = 1$.

$$\bar{S} \cdot \bar{E} \cdot \bar{S} \cdot \bar{I} \cdot \bar{E} \cdot \bar{S}.$$

(2.3)

By taking $\bar{S} \cdot \bar{E} \cdot \bar{S}$ and reflecting it back again, we obtain

$$\bar{S} \cdot \bar{E} \cdot \bar{S} \cdot \bar{I} \cdot \bar{S} \cdot \bar{E}.$$

(2.4)

We now derive a few special relations for the special elements we have in the subsequent analysis. Let \bar{I} and \bar{S} be arbitrary vectors and \bar{I} the unit vector. Then

$$\bar{I} \cdot \bar{S} \cdot \bar{I} \cdot \bar{S} \cdot \bar{I} \cdot \bar{S} \cdot \bar{I} \cdot \bar{S}$$

$$= \bar{I} \cdot \bar{S}$$

$$= \bar{I} \cdot \bar{S} \cdot \bar{I}$$

(2.5)

Since \bar{I} and \bar{S} are arbitrary vectors

$$\bar{I} \cdot \bar{S} \cdot \bar{I} = \bar{S}$$

(2.6)

Similarly we can find the relation between \bar{S} and \bar{E} .

$$\bar{S} \cdot \bar{E} \cdot \bar{I} \cdot \bar{S} \cdot \bar{E} \cdot \bar{I}$$

$$= \bar{S} \cdot \bar{E} \cdot \bar{I}$$

$$= \bar{S} \cdot \bar{E} \cdot \bar{I} \cdot \bar{S}$$

$$= \bar{S} \cdot \bar{E} \cdot \bar{I} \cdot \bar{S} \cdot \bar{E}$$

$$= \bar{S} \cdot \bar{E} \cdot \bar{I} \cdot \bar{S}$$

(2.7)

$$\bar{B}_2 = \bar{I} + \bar{B}_3 - \bar{B}_4$$

C.11

By using Eqs. C.11 and C.12, we get

$$\bar{B}_2 = \bar{I} + \bar{B}_3 - \bar{B}_4 \cos^2 \theta - \bar{B}_5 \sin^2 \theta \quad \text{C.13}$$

C.13

where \bar{B}_5 is as defined by Eq. 3.1. We also have

$$\frac{\partial \bar{B}_5}{\partial \theta} \cdot \bar{I} = - \bar{B}_3 \cos^2 \theta - \bar{B}_5 \sin^2 \theta. \quad \text{C.14}$$

Thus, from Eqs. C.13 and C.14 we get

$$\bar{I} = \bar{I}(\theta).$$

C.15

Equation C.15 can be expressed in terms of \bar{B}_2

$$\bar{B}_2 = \bar{I} + \bar{B}_3 - \bar{B}_4 \cos^2 \theta. \quad \text{C.16}$$

C.16

By a direct cosine multiplication of Eq. C.16 with \bar{I} , we get the following two relations

$$\bar{B}_2 \cdot \bar{I} = \bar{I} \quad \text{C.17}$$

C.17

$$\bar{B}_2 \cdot \bar{B}_2 = \bar{I} \quad \text{C.18}$$

C.18

3.1.2. Inverse Relation: Inverse of Functions

In this section we shall obtain a complete expression for the inverse relation of the function $\bar{I} = \bar{I}(\theta)$. At this time the pertinent inverse relation function (Eq. 3.1) is unknown.

$$C_1(\bar{I}, \bar{B}_2) = \frac{1}{\pi} \int_{-\pi}^{\pi} d\theta (\bar{I} - \bar{B}_2 \cos \theta - \frac{\bar{B}_3}{\sin \theta}) \quad \text{C.19}$$

above

$$I = - \frac{2e}{\pi} s + \frac{\bar{q} \cdot \vec{B}(s) \cdot \vec{s}}{s_c} .$$

The charge density can be obtained by integration of (C.19).

$$\therefore \bar{s}_3 = - \frac{e^2}{\pi s_c} \int_1^s \approx \int d\bar{s} \bar{s} \cdot \bar{s} \cdot \frac{2e}{\pi s_c} s^2 . \quad (C.21)$$

By partial integration in \bar{s} , we obtain

$$\begin{aligned} \therefore \bar{s}_3 &= - \frac{e^2}{\pi s_c} \int_1^s \approx \int_{s_1}^s \bar{s} \cdot \bar{s} \cdot \bar{s} \cdot \frac{2e}{\pi s_c} s^2 \\ &\quad + \frac{e^2}{\pi s_c} \int_{s_1}^s \approx \int d\bar{s} \bar{s} \cdot \bar{s} \cdot \bar{s} \cdot \bar{s} \cdot \bar{s} . \quad (C.22) \end{aligned}$$

The polarization charge associated with a plane wave is given by

$$\bar{s}_3 = \bar{s} \cdot \bar{s} \cdot \bar{s} . \quad (C.23)$$

We note again that the local charge \bar{s} is related to s_3 and \bar{s} through Eq. (C.17) above.

$$\bar{s} \cdot \frac{e^2}{\pi s_c} \int_1^s \approx \int d\bar{s} \bar{s} \cdot \bar{s} \cdot \bar{s} \cdot \bar{s} . \quad (C.24)$$

The first order plasma current can be obtained by the following integration

$$\begin{aligned} \langle \bar{s} \rangle &= - \int \bar{s} \bar{s} \cdot \bar{s} \cdot \bar{s} d\bar{s} \\ &= - \frac{e^2}{\pi s_c} \int_1^s \approx \int d\bar{s} \bar{s} \cdot \bar{s} \cdot \bar{s} \cdot \bar{s} \cdot \bar{s} . \quad (C.25) \end{aligned}$$

remaining after $\mathbf{i}\mathbf{k} \times \tilde{\mathbf{B}}$ is subtracted from Eq. (C.26), vanish. We show that this is indeed the case. Let

$$\tilde{\mathbf{A}} = i\omega \tilde{\mathbf{P}} - \langle \rho \tilde{\mathbf{v}} \rangle - i\mathbf{k} \times \tilde{\mathbf{B}}.$$

Then

$$\tilde{\mathbf{A}} = \frac{e^2}{m_e} \int_1^\infty \alpha \int e^{2\pi i \mathbf{k} \cdot \tilde{\mathbf{r}}} e^E f_0(\tilde{\mathbf{r}}) \left[\frac{i\omega \tilde{\mathbf{P}}}{m_e} - \mathbf{I} - \frac{i(\mathbf{k} \cdot \mathbf{I} + \tilde{\mathbf{v}})}{m_e} \frac{\tilde{\mathbf{r}}}{L} \right] \cdot (\tilde{\mathbf{E}} \cdot \tilde{\mathbf{B}}) \quad (C.30)$$

Since $\mathbf{I} = \tilde{\mathbf{L}}' + \tilde{\mathbf{L}} \times \tilde{\mathbf{v}}$ from (C.17), we have

$$\begin{aligned} \tilde{\mathbf{A}} &= \frac{e^2}{m_e} \int_1^\infty \alpha \int e^{2\pi i \mathbf{k} \cdot \tilde{\mathbf{r}}} f_0(\tilde{\mathbf{r}}) \left[\frac{i\omega \tilde{\mathbf{P}}}{m_e} - \mathbf{I} - \frac{i(\mathbf{k} \cdot \tilde{\mathbf{L}}' + \tilde{\mathbf{v}})}{m_e} \frac{\tilde{\mathbf{r}}}{L} - \frac{i\mathbf{k} \cdot (\tilde{\mathbf{L}} \times \tilde{\mathbf{v}}) \cdot \tilde{\mathbf{v}}}{m_e} \frac{\tilde{\mathbf{r}}}{L} \right] \cdot \tilde{\mathbf{E}} \cdot \tilde{\mathbf{B}} \\ &+ \frac{e^2}{m_e} \int_1^\infty \alpha \int e^{2\pi i \mathbf{k} \cdot \tilde{\mathbf{r}}} f_0(\tilde{\mathbf{r}}) \left[\frac{2\pi i}{\lambda} \frac{\tilde{\mathbf{L}}}{L} + \mathbf{I} e^E + e^E \frac{i\mathbf{k} \cdot (\tilde{\mathbf{L}} \times \tilde{\mathbf{v}}) \cdot \tilde{\mathbf{v}}}{m_e} \frac{\tilde{\mathbf{r}}}{L} \right] \cdot \tilde{\mathbf{E}} \cdot \tilde{\mathbf{B}}. \end{aligned} \quad (C.31)$$

Partial integration in $\tilde{\mathbf{r}}$ of the first term yields

$$\begin{aligned} \tilde{\mathbf{A}} &= \frac{e^2}{m_e} \int_1^\infty \alpha \int e^{2\pi i \mathbf{k} \cdot \tilde{\mathbf{r}}} f_0(\tilde{\mathbf{r}}) \left[-\tilde{\mathbf{I}} \cdot (\tilde{\mathbf{E}} \cdot \tilde{\mathbf{L}}') - \tilde{\mathbf{I}} \cdot (\tilde{\mathbf{E}} \cdot \tilde{\mathbf{L}}) + \tilde{\mathbf{I}} \cdot \tilde{\mathbf{L}}' \right. \\ &\quad \left. + \left\{ \frac{i\mathbf{k} \cdot (\tilde{\mathbf{L}} \times \tilde{\mathbf{v}}) \cdot \tilde{\mathbf{v}}}{m_e} \right\} \tilde{\mathbf{L}} \cdot (\tilde{\mathbf{E}} \cdot \tilde{\mathbf{L}}') \right]. \end{aligned} \quad (C.32)$$

Let the first three terms of the integrand be $-\tilde{\mathbf{C}}$. Then

$$\tilde{\mathbf{C}} = i_0 e^{E_0} (\mathbf{I} \cdot (\tilde{\mathbf{E}} \cdot \tilde{\mathbf{L}}') - (\mathbf{I} \cdot \tilde{\mathbf{L}}) \cdot (\tilde{\mathbf{E}} \cdot \tilde{\mathbf{L}}')). \quad (C.33)$$

By using Eqs. (C.17), (C.18), and (C.19), we get

$$\begin{aligned} \tilde{\mathbf{C}} &= i_0 e^{E_0} (\mathbf{I} \cdot (\tilde{\mathbf{E}} \cdot \tilde{\mathbf{L}}') - (\mathbf{I} \cdot \tilde{\mathbf{L}}) \cdot (\tilde{\mathbf{E}} \cdot \tilde{\mathbf{L}}')) \\ &= i_0 e^{E_0} (\mathbf{I} \cdot (\tilde{\mathbf{E}} \cdot \tilde{\mathbf{L}}') - \mathbf{I} \cdot (\mathbf{G} \cdot \tilde{\mathbf{L}}) \cdot (\tilde{\mathbf{E}} \cdot \tilde{\mathbf{L}}')) \\ &= i_0 e^{E_0} (\mathbf{I} \cdot (\tilde{\mathbf{E}} \cdot \tilde{\mathbf{L}}') - \mathbf{I} \cdot (\mathbf{G} \cdot (\mathbf{I} \cdot \tilde{\mathbf{L}}))) \\ &= 0. \end{aligned}$$

a subdivision as simple as that described in (2) cannot be accomplished. However, if we ignore forces of the order $\vec{v} \cdot \vec{B}$ as compared with \vec{I} then the problem simplifies, and in fact the procedure to separate the currents is identical to that followed in Section (2). The result is again given by Eqs. (C.24) and (C.25) where now $I_0(\vec{v})$ is as defined in (C.35). For electrostatic waves the approximation $\vec{v} \cdot \vec{B} = 0$ should be very good.

APPENDIX B. THE ELECTRIC SUSCEPTIBILITY TENSOR FOR
NONUNIFORM ELECTRON PLASMAS

It was appropriate to evaluate the electric susceptibility tensor appropriate for nonuniform electron plasma. In particular, we express the tensor elements in terms of the Gilbert functions of the plasma as tabulated by Price and Chen. The susceptibility tensor for the case of nonuniform temperature is given in Section 3.1. The case of nonisotropic temperature can be treated by a simple modification of the procedure followed for the nonuniform case. In Section 3.2 the results for the nonisotropic case are given without derivation. Some useful properties of the Gilbert functions of the plasma are given in Section 3.3.

3.1. Nonuniform Temperature Susceptibility Tensor

From Eq. (2.2) we have

$$2 \cdot \frac{e^2}{m} \int_{-\infty}^{\infty} e f \bar{n} - \left[\frac{e^2}{m} \cdot \frac{\partial \bar{n}}{\partial E} \right] \bar{n} \cdot \bar{n} = 2 \cdot \frac{e^2}{m} \bar{n} \cdot \bar{n}$$

The distribution function and the nonisothermal condition are given by

$$e \bar{n} = e \exp \left[\frac{-E}{kT} \right]. \quad 3.1$$

$$\int e \bar{n} d\bar{n} = 1. \quad 3.2$$

Introducing Eq. 3.2 into Eq. 3.1, we obtain

$$2 \cdot \frac{e^2}{m} \int_{-\infty}^{\infty} e \bar{n} \cdot \bar{n} - \left[\frac{e^2}{m} \right] \int \bar{n} - \left[\frac{e^2}{m} \cdot \frac{\partial \bar{n}}{\partial E} \right] \bar{n}. \quad 3.3$$

The velocity integral of Eq. 3.3.4 can be performed and the result is given as

$$2 \cdot \frac{e^2}{m} \int_{-\infty}^{\infty} e \bar{n} \cdot \bar{n} - \left[\frac{e^2}{m} \cdot \frac{1}{2} \frac{d}{dE} \bar{n}^2 \right]. \quad 3.4$$

A direct summation of \vec{E} over T gives

$$\vec{E} = \{i_x \cdot \vec{i}\} \cdot \vec{\epsilon}_x^2 \vec{\epsilon}_{xy} - \vec{\epsilon}_{xy} \cdot \vec{i} + i_y \cdot \vec{i} + \vec{i} \cdot \vec{i} (1 - \cos \theta) \\ - \vec{i} \cdot \vec{i} \cdot \vec{i}. \quad (D.6)$$

In terms of Cartesian coordinates we obtain

$$\vec{E} = \vec{\epsilon}_x^2 \vec{\epsilon}_{xy} + i_x \vec{\epsilon}_y + \vec{\epsilon}_{xy} \cdot i_x \cos \theta - i_y (1 - \cos \theta) \\ + i_y \vec{\epsilon}_y + \vec{\epsilon}_y \cdot i_x + \vec{\epsilon}_y (1 - \cos \theta). \quad (D.7)$$

Now i_x , i_y , and i_z are unit vectors along x , y and z axes respectively and the ex magnetic field direction along the z axis. The electric susceptibility tensor defined by

$$\vec{E} = \epsilon_0 \vec{\epsilon} \cdot \vec{B} \quad (D.8)$$

$$\vec{\epsilon} = \begin{bmatrix} \epsilon_{xx} & \epsilon_{xy} & \epsilon_{xz} \\ \epsilon_{yx} & \epsilon_{yy} & \epsilon_{yz} \\ \epsilon_{zx} & \epsilon_{zy} & \epsilon_{zz} \end{bmatrix}$$

$$E_x = \epsilon_{yy} + \frac{1}{2} \int_{\text{cyl}} \cos \theta e^{-kz} d\sigma \quad (D.9)$$

$$E_y = \frac{1}{2} \int_{\text{cyl}} z e^{-kz} d\sigma \quad (D.10)$$

$$E_z = \epsilon_{yy} - \frac{1}{2} \int_{\text{cyl}} (1 - \cos \theta) e^{-kz} d\sigma. \quad (D.11)$$

$$\begin{aligned} &= \frac{\pi}{a_c} - \frac{k^2 v_0^2}{a_c^2} (k_1^2 - k_2^2) \\ &= \frac{\pi}{a_c} + \frac{k_1^2 v_0^2}{a_c^2} \sin^2 t + \frac{k_2^2 v_0^2}{a_c^2} (1 - \cos 2t). \end{aligned}$$

There are four types of integrals to be evaluated

$$S_1(k_1, k_2, \mu) = \int_0^\pi e^{-\mu t} dt \quad (D.12)$$

$$S_2(k_1, k_2, \mu) = \int_0^\pi t e^{-\mu t} dt \quad (D.13)$$

$$S_3(k_1, k_2, \mu) = \int_0^\pi \sin t e^{-\mu t} dt \quad (D.14)$$

$$S_4(k_1, k_2, \mu) = \int_0^\pi \cos t e^{-\mu t} dt. \quad (D.15)$$

However, all of the integrals can be obtained from one integral S_1 due to the following relations:

$$S_3(k_1, k_2, \mu) = \frac{S_1(k_1, k_2, \mu - a_c) - S_1(k_1, k_2, \mu + a_c)}{2a} \quad (D.16)$$

$$S_4(k_1, k_2, \mu) = \frac{S_1(k_1, k_2, \mu - a_c) + S_1(k_1, k_2, \mu + a_c)}{2}, \quad (D.17)$$

and by partial integration of the following integral

$$\int_0^\pi \left(\frac{ka}{a_c} + \frac{k^2 v_0^2}{a_c^2} t + \frac{k^2 v_0^2}{a_c^2} \sin t \right) e^{-\mu t} dt$$

one obtains

$$\cdots - \frac{1}{s_c} S_1(k_1, k_2, \mu) - \frac{k_1^2 v^2}{s_c^2} S_2(k_1, k_2, \mu) - \frac{k_1^2 v^2}{s_c^2} S_3(k_1, k_2, \mu). \quad (D.14)$$

In addition the following relation is also true.

$$S_2(k_1, k_2, \mu) = - \frac{s_c}{2} \frac{\partial}{\partial s} S_1(k_1, k_2, \mu). \quad (D.15)$$

Thus the only integral needed is S_1 , which we shall evaluate now. Let us first introduce the variables

$$\begin{aligned} \frac{v^2}{2} &= \frac{k_1^2 v^2}{s_c^2} \\ v^2 &= \frac{k_1^2 s}{s_c^2}, \quad s = \frac{k_1 v}{\sqrt{2} s_c} \\ p_s &= \sqrt{\left(\frac{s}{s_c}\right)^2 - 1} \end{aligned}$$

and use the well-known expansion

$$-\left[-\frac{1}{2} \cos \varphi \right] = \sum_{n=0}^{\infty} I_n \left(\frac{1}{2} \right) e^{i n \varphi} \quad (D.16)$$

where I_n are the modified Bessel functions. Then S_1 becomes

$$S_1 = \sum_{n=0}^{\infty} \exp \left[-\frac{1}{2} \right] I_n \left(\frac{1}{2} \right) \int_0^{\infty} d\varphi \cdot e^{-\alpha^2 \varphi^2 - p_s^2 \varphi^2} \quad (D.17)$$

We now change the integration variable to $s = \pm \alpha \varphi$, where the sign is fixed such that $s > 0$ for $\varphi > 0$, and obtain

$$s_1 = \sum_{n=0}^{\infty} -\left[\frac{1}{2} \right] I_n \left(\frac{1}{2} \right) \int_{-\infty}^{\infty} \frac{e^{-x^2}}{x^2 + \left[s^2 - \left(\frac{k_1^2}{2} \right) \right]} \quad (D.22)$$

The integral can be expressed in terms of the confluent hypergeometric function, $I_0(s, k_1^2; c)$, first introduced by Tricomi.⁵⁷

$$s_1 = \sum_{n=0}^{\infty} -\left[\frac{1}{2} \right] I_n \left(\frac{1}{2} \right) \left[\frac{1}{(2n+1)} \cdot \left\{ \frac{1}{2}, \frac{1}{2}, \left(\frac{k_1^2}{2} \right)^2 \right\} \right] \quad (D.23)$$

With these particular parameters, s_1 can also be expressed in terms of the bilateral transform of the gamma function defined by Prudnikov and Coorte.⁴⁵

$$\alpha(\zeta) = z^{-1/2} \int_{-\infty}^{\infty} \frac{e^{-x^2}}{x^2 + \zeta} \quad \text{Im } \zeta > 0 \quad (D.24)$$

Let us define a new variable

$$\zeta_n = \frac{\frac{z-m_c}{k_1 v_0}}{\sqrt{2}} \quad (D.25)$$

Then $\text{Ai}\left(\frac{1}{2}, \frac{1}{2}, -\zeta^2\right) = Z(\zeta)$ as can be shown by comparing the power series expansions of $Z(\zeta)$ and $\text{Ai}\left(\frac{1}{2}, \frac{1}{2}, -\zeta^2\right)$. The function $Z(\zeta)$ is defined such that it is regular for $\text{Im } \zeta > 0$, in other words, when

$$\text{Im} \left(\frac{\frac{z-m_c}{k_1 v_0}}{\sqrt{2}} \right) > 0 \quad (D.26)$$

Since on a Laplace integral path $\text{Im } x < 0$, the inequality of (D.26) requires that $k_1 < 0$, which makes $\alpha < 0$. Thus the negative sign in front of α must be selected in order to keep $s > 0$ in (D.22), and so

$$s_1(k_1, k_1 v_0) = \frac{-\sqrt{2} \alpha_c}{k_1 v_0} \sum_{n=0}^{\infty} \exp\left[-\frac{\lambda^2}{2}\right] I_n\left(\frac{1}{2}\right) Z(\zeta_n) \quad (D.27)$$

Then (D.27) is reduced into Eqs. (D.15) through (D.19), the elements of the dielectric susceptibility tensor become

$$\epsilon_{xx} = \epsilon_{yy} = \frac{e^2 n_0}{2\omega_c^2} \left[-\frac{1}{2} \right] \sum_{m=1}^{\infty} I\left(\frac{1}{2}\right) z_m z_{m-1}, \quad (D.28)$$

$$\epsilon_{zz} = -\frac{e^2 n_0}{2\omega_c^2} \left[-\frac{1}{2} \right] \sum_{m=1}^{\infty} I\left(\frac{1}{2}\right) z_m^2, \quad (D.29)$$

$$\epsilon_{xy} = -\epsilon_{yz} = -\frac{e^2 n_0}{2\omega_c^2} \left[-\frac{1}{2} \right] \sum_{m=1}^{\infty} I\left(\frac{1}{2}\right) \left[z_m - \frac{z_{m+1} z_{m-1}}{2} \right], \quad (D.30)$$

where $z_m = Z(\zeta_m)$.

c. Anisotropic Maxwellian Velocity Distribution with Drift

By assuming the forces of the order $\vec{v} \times \vec{B}$ to be negligible as compared to E , the polarization vector is again given by Eq. (D.1), where now for the anisotropic drifting Maxwellian velocity distribution we have

$$f_0(\vec{v}) = A \exp \left[-\frac{m}{2kT_1} (v_1 - v_{01})^2 - \frac{m}{2kT_2} v_2^2 \right]. \quad (D.31)$$

With (D.31) the velocity integral in (D.1) can be performed to give

$$\vec{P} = \frac{e^2 n_0}{2\omega_c^2} \int d\vec{v} \cdot \vec{v} \cdot (\vec{E} \cdot \vec{L}) \exp \left[-\frac{1}{2kT_1} \frac{(v_1 - v_{01})^2}{m} - \frac{k^2 v_2^2}{2m} - \frac{k^2 v_{01}^2}{m} (1 - \cos \phi) \right] \quad (D.32)$$

where

$$\frac{v_2}{v_{01}} = \frac{\sin \phi}{2}$$

and

$$\frac{v_{01}}{v_1} = \frac{\sin \phi}{2}$$

In terms of the Hilbert transform of the gammas, we have

$$z_{xy} = z_{yx} = \frac{\alpha^2}{2\sqrt{z} k_c h_1 v_1} \Rightarrow \left[-\frac{1}{2} \right] \sum_{n=1}^{\infty} i \left(\frac{1}{2} \right) [x_{n+1} - x_{n-1}] \quad (D.33)$$

$$z_{xx} = -\frac{\alpha^2}{2k_c^2 v_1^2} \Rightarrow \left[-\frac{1}{2} \right] \sum_{n=1}^{\infty} i \left(\frac{1}{2} \right) x_n^2 \quad (D.34)$$

$$z_{yy} = -z_{yx} = \frac{-\alpha^2}{\sqrt{z} k_c h_1 v_1} \Rightarrow \left[-\frac{1}{2} \right] \sum_{n=1}^{\infty} i \left(\frac{1}{2} \right) [x_n - \frac{x_{n+1} + x_{n-1}}{2}] \quad (D.35)$$

where

$$x_n = Z(\zeta_n),$$

$$\zeta_n = \frac{n - h_1 v_1 - m_c}{\sqrt{2} k_c h_1 v_1},$$

$$\frac{1}{2} = \frac{k_c^2 v_1^2}{2}.$$

3. Properties of $Z(\zeta)$

The function $Z(\zeta)$ is defined by the integral of Eq. (D.24) when $\operatorname{Im} \zeta > 0$. In the lower ζ plane $Z(\zeta)$ and its n^{th} derivative $Z^{(n)}(\zeta)$ are given by their analytic continuation

$$Z^{(n)}(\zeta) = [Z^n(\zeta)]^* + 2i\sqrt{\pi} (-1)^n h_n(\zeta) \exp(-\zeta^2) \quad (D.36)$$

where $h_n(\zeta)$ are the Hermite polynomials⁵⁸ satisfying the recurrence relation

$$h_n(\zeta) = -2\zeta h_{n-1}(\zeta) - h'_{n-1}(\zeta) \quad \text{with } h_0(\zeta) = 1.$$

The function $Z(\zeta)$ satisfies the following differential equation

$$z'(\zeta) + 2\zeta z(\zeta) + 2 = 0 \quad (D.37)$$

and the symmetry relation

$$z^{(n)}(-\zeta^*) = (-1)^{n+1} [z^{(n)}(-\zeta)]^*. \quad (\text{D.38})$$

$z(\zeta)$ can be expanded in terms of the power series

$$z(\zeta) = 1/\sqrt{x} e^{-\zeta^2} - 2x \left[1 - \frac{2}{3} \zeta^2 + \frac{4}{15} \zeta^4 - \dots + \frac{(-1)^{n+1} \sqrt{x}}{2(n+1/2)!} \zeta^{2n+2} + \dots \right] \quad (\text{D.39})$$

and the asymptotic expansion

$$z(\zeta) \sim 1/\sqrt{x} e^{-\zeta^2} - \frac{1}{\zeta} - \frac{1}{\zeta^3} - \dots - \frac{(n-1/2)!}{\sqrt{x} \zeta^{2n+1}} \quad (\text{D.40})$$

where

$$A = \begin{cases} 1 & \text{Im } \zeta > 0 \\ 1 & \text{Im } \zeta = 0 \\ 2 & \text{Im } \zeta < 0 \end{cases}$$

For computational purposes, the continued fraction expansions are useful:⁴² if $|\zeta|$ is small,

$$z'(\zeta) = 12\sqrt{x} \zeta e^{-\zeta^2} - 2 \left[\frac{1}{1 + 1/2} - \dots - \frac{n^2}{2n-1/2} + \frac{(n-1/2)\zeta^2}{2n+1/2} - \dots \right] \quad n \geq 1 \quad (\text{D.41})$$

or if $|\zeta|$ is large,

$$z'(\zeta) = \frac{1}{-\zeta^2 + 3/2 + \dots} \frac{-(1-1/2n)}{2 - \zeta^2/n - 1/2n + \dots} \quad \begin{matrix} \text{Im } \zeta > 0 \\ n \geq 2 \end{matrix} \quad (\text{D.42})$$

To obtain the relation equivalent to Eq. (D.42) for $\text{Im } \zeta < 0$, we use Eq. (D.36). Continued fraction expansions are useful in the intermediate range of $|\zeta|$, i.e., $2 < |\zeta| < 8$, where neither the power series expansion nor the asymptotic expansion are satisfactory.

APPENDIX E. RELATION BETWEEN \vec{B} AND \vec{H} FOR A MAXWELLIAN PLASMA

For a plasma with isotropic temperature, the magnetization vector as defined by Eq. (C.24) can be expressed in terms of the magnetic induction \vec{B} . Equation (C.24) is given by

$$\vec{M} = -\frac{e^2}{m\omega_c^2} \int_0^\infty d\varphi \int e^{i\vec{k}\cdot\vec{v}} \times \vec{L} \cdot (\vec{E}\cdot\vec{L}') f_0(\vec{v}) d^3v \quad (C.24)$$

For a Maxwellian distribution we have

$$\vec{v} \cdot f_0(\vec{v}) = -v_\theta^2 \frac{\partial f_0(\vec{v})}{\partial \vec{v}} . \quad (E.1)$$

By introducing (E.1) into (C.24) we obtain

$$\vec{M} = -\frac{e^2 v_\theta^2}{m\omega_c^2} \int_0^\infty d\varphi \int e^{i\vec{k}\cdot\vec{v}} \left[\frac{\partial f_0(\vec{v})}{\partial \vec{v}} \times \vec{L} \cdot (\vec{E}\cdot\vec{L}') \right] d^3v . \quad (E.2)$$

Partial integration in \vec{v} yields

$$\vec{M} = -\frac{e^2 v_\theta^2}{m\omega_c^2} \int_0^\infty d\varphi \int d^3v f_0(\vec{v}) e^{i\vec{k}\cdot\vec{v}} [i\vec{k} \cdot \vec{L} \times \vec{L} \cdot (\vec{E}\cdot\vec{L}')] . \quad (E.3)$$

The velocity integrals can be performed with the result

$$\vec{M} = -\frac{e^2 v_\theta^2}{m\omega_c^2} \int_0^\infty d\varphi i\vec{k} \cdot \vec{L} \times \vec{L} \cdot (\vec{E}\cdot\vec{L}') \exp \left[-\frac{i\omega\varphi}{\omega_c} - \frac{v_\theta^2 \Phi^2}{2\omega_c^2} (\vec{k}\cdot\vec{L})^2 \right] . \quad (E.4)$$

From Eq. (D.6) we have

$$\vec{k} \cdot \vec{L} \times \vec{L} \cdot (\vec{E}\cdot\vec{L}') = -\vec{k} \cdot \vec{L}(\varphi) \times \vec{L}(-\varphi) \cdot \vec{E} . \quad (E.5)$$

By directly substituting the definition of $\tilde{L}(\varphi)$ into (B.5), one obtains the relation

$$\hat{\mathbf{k}} \cdot \tilde{\mathbf{L}}(\varphi) \times \tilde{\mathbf{L}}(-\varphi) + \hat{\mathbf{k}} = \tilde{\mu}(\varphi) + i\hat{\mathbf{k}} \times \hat{\mathbf{k}} \quad (B.6)$$

where

$$\tilde{\mu}(\varphi) = \hat{\mathbf{n}} \cdot \hat{\mathbf{n}}' (1 - \cos \varphi) + (1 - \hat{\mathbf{n}} \cdot \hat{\mathbf{n}})\varphi \sin \varphi + (\hat{\mathbf{n}} \times \hat{\mathbf{l}})\varphi(1 - \cos \varphi). \quad (B.7)$$

Maxwell's equation gives

$$\hat{\mathbf{k}} \times \hat{\mathbf{k}} = \sigma \hat{\mathbf{s}}$$

Hence,

$$\begin{aligned} \hat{\mathbf{k}} &= \frac{i\omega^2 v_B^2 \mu_0}{m_c^3} \int_0^\pi \tilde{\mu}(\varphi) \cdot \hat{\mathbf{k}} \exp\left[-\frac{i\omega}{m_c} - \frac{v_B^2}{2m_c^2} (\hat{\mathbf{k}} \cdot \hat{\mathbf{l}})\right] d\varphi \\ &= \frac{i\omega^2 v_B^2}{m_c^3 \mu_0} \int_0^\pi \tilde{\mu}(\varphi) \cdot \hat{\mathbf{k}} \exp\left[-\frac{i\omega}{m_c} - \frac{v_B^2}{2m_c^2} (\hat{\mathbf{k}} \cdot \hat{\mathbf{l}})\right] d\varphi. \end{aligned} \quad (B.8)$$

Thus for a Maxwellian plasma with isotropic temperature, the magnetization vector can be expressed in terms of $\hat{\mathbf{B}}$.

The next floating procedure works only if the total radius are near a unit. Then the program is started at a point where the total radius is either zero or one to generate easily all the very important initial values α_1 , α_2 and α_3 are not far from a zero. Once the total radius is found, it is changed by a small amount and α_1 , α_2 and α_3 are changed as the next iteration in the flow diagram. At this stage the roots can be found with great accuracy they are not easily obtained or known.

1. Numerical Work in the Program for "Surface Plots"

In Section 1 we discussed the overall procedure to find the roots of the dispersion relation. In this section we describe the manner in which the various subroutines are computed.

a. Initial conditions of the problem. S_0^{in} :

A Fortran program developed by DeWolf and Barnes⁴ is used to compute S_0^{in} .

b. Dispersed Surface Functions. $J_1(k, b)$

The series expansion of J_1 is used. The argument of the function $k^2/2$ is small enough in our calculations to enable us to use the power series expansion.

c. The value of the General Functions $J_1(k, b), J_0(k, b)$:

A continued fraction expansion⁵ given by

$$\frac{J_1(k)}{J_0(k)} = \frac{1}{2} - \frac{k^2}{4} + \frac{k^2}{2} - \cdots - \frac{k^2}{2n} - \cdots \quad (E.1)$$

is used to compute the ratios for $0 < |k|b < 17$. For $|k|b > 17$, asymptotic series are used to compute $J_1(k, b)$ and $J_0(k, b)$.

d. Rooted Functions I_0 and I_1 :

For the cases with finite waveguide radius, a program based on power series and asymptotic expansions written by J. Simpson⁶ is used. For $a = \infty$, Eq. (E.1) reduces to

$$S = k \epsilon \frac{J_1(k/b)}{\int_{-1}^1 J_0(k/b)} - ik \epsilon \frac{E_1(ik/b)}{\int_{-1}^1 E_0(ik/b)} . \quad (F.5)$$

For this case a continued fraction expansion for E_0/E_1 developed by Borfler is used in the range $|ik/b| \geq 1.5$.

The continued fraction is given by

$$\begin{aligned} -ix \frac{E_1(ix)}{E_{n+1}(ix)} &= x \frac{E_n(x)}{E_{n+1}(x)} = (2n-2n-1) + \frac{(1+2n)(3/2+n)(1/2)}{1+x} \\ &\quad - \frac{(1/2-n)(5/2-n)1/4}{2+x} - \frac{(3/2-n)(7/2+n)1/4}{3+x} - \dots \end{aligned} \quad (F.6)$$

For smaller values of $|x|$, power series representations for E_1 and E_0 are used.

3. Functions Used in the Program for Ions

For waves near the ion cyclotron and ion plasma frequencies, the wave numbers k_{\perp} are very small as compared to $|k_z|$, making the wave propagation almost perpendicular to the column. In a certain range of small k_{\perp} , $|k_z|$ becomes so large that a prohibitive number of terms has to be taken in the series representation of the ions susceptibility.

We saw in Appendix D that only one integration is needed to evaluate the susceptibility tensor elements, i.e.,

$$S_{11} = \int_0^\infty d\tau \exp \left[-\frac{i\omega\varphi}{\omega_{ci}} - \frac{k_{\parallel}^2 v_{\theta 1}^2 \varphi^2}{2\omega_{ci}^2} - \frac{k_{\perp}^2 v_{\theta 1}^2}{\omega_{ci}^2} (1 - \cos \varphi) \right] . \quad (F.7)$$

This integral represents a Laplace transform of a product of two functions,

$$q_1(\varphi) = \exp \left[-\frac{k_{\parallel}^2 v_{\theta 1}^2}{2\omega_{ci}^2} \varphi^2 \right] \quad (F.8)$$

$$a_2(\varphi) = \exp \left[-\frac{\frac{k^2 v^2}{2} \theta_i^2}{\omega_{ci}^2} (1 - \cos \varphi) \right] \quad (F.9)$$

and, hence, the convolution theorem can be used in its evaluation. The result of this procedure is given by

$$S_{11} = \int_{-\infty}^{\infty} \frac{\exp \left[-\left(w/x_1 \right)^2 \right]}{x_1 \sqrt{\pi}} J_1 \left(v - w, \frac{\lambda^2}{2} \right) dw \quad (F.10)$$

where

$$x_1^2 = \frac{2k^2 v^2 \theta_i^2}{\omega_{ci}^2}$$

$$\frac{\lambda_1^2}{2} = \frac{k^2 v^2 \theta_i^2}{\omega_{ci}^2}$$

$$v = \frac{\omega}{\omega_{ci}}$$

and

$$J_1 \left(v, \frac{\lambda^2}{2} \right) = \int_0^{\infty} \exp \left[i v \varphi - \frac{\lambda_1^2}{2} (1 - \cos \varphi) \right] d\varphi. \quad (F.11)$$

The integral for purely transverse propagation $J_1[v, (\lambda^2/2)]$ has been evaluated by Derfler⁴⁹ in terms of Nielson's cylinder function.⁶³ A fast computer program based on this result is used to find $J_1[v, (\lambda^2/2)]$. The integral of Eq. (F.10) is then evaluated by the Gauss-Hermite quadrature formula.⁶⁴ This technique is particularly good when the quantity x_1 is very small in which case $\exp[-(v/x_1)^2]/(\sqrt{\pi} x_1)$ approximates a Dirac delta function.

The entire program was written in S⁺BALGOL which is the Stanford version of ALGOL 60.

13. ABSTRACT This report deals with the study of electrostatic waves in bounded hot plasma and, except for a few dc measurements, is theoretical. The study is broadly divided into two parts. The first section investigates waves in a diode system with no dc magnetic field applied. A dc analysis of the equilibrium plasma produced within a thermionic diode is undertaken to provide a basis for the rf analysis, and expected plasma densities in the diode are computed for a variety of practical situations. Electrostatic wave resonances in the diode are predicted by using the hydrodynamic model for the nonuniform plasma. The impe- dence of a uniform plasma diode is obtained by using a kinetic model of the plasma. This model enables us to take into account the end plate electron absorption loss, a process similar to that which causes end plate diffusion in the Q-machine. The absorption loss is found to have a large effect on the impedance of the diode. The second part of the report deals with the study of guided waves along a cylindrical column of Maxwellian plasma in a magnetic field. A dc study of the plasma column is first conducted. Theoretical density and current profiles are ob- tained and are compared with the measured results. Since an rf analysis using a self-consistent dc solution is quite involved, the plasma column is approximated by a uniform plasma with sharp boundary and no drift. To obtain the rf fields in such a column, a plane-wave solution for an infinite Maxwellian plasma in an applied magnetic field is first obtained. By superimposing infinitely many plane waves, the fields within the column are constructed, and by matching the appropriate fields at the boundary, a dispersion relation is derived.

ELECTROSTATIC WAVES IN BOUNDED HOT PLASMAS

Abstract - Page 2

The solutions to the dispersion relation reveal the existence of a new type of unstable wave. When only the electrons are assumed to respond to the electric field, the surface waves which propagate when $\omega_{ce} < \omega_{pe}$ are found to be unstable. When the ion motion is included, additional unstable surface waves are obtained whenever $\omega_{ci} < \omega_{pi}$. A study of the instability shows that it is due to finite Larmor radii effects and is driven by the transverse energy of the particles.

While the "electron" surface wave instability is relatively weak and can easily be stabilized by making $\omega_{ce} > \omega_{pe}$, the "ion" surface wave instability is found to be very strong, and the stabilizing condition of $\omega_{ci} > \omega_{pi}$ is not easily attained in high density plasmas such as those in fusion machines. Thus, the unstable ion surface waves may have a serious effect on the containment of the fusion plasma.

INSTRUCTIONS				
1. ORIGINATING ACTIVITY. Enter the name and address of the originating, administrative, general, Department of Defense activity or other organization responsible for writing the report.				
2. REPORT SECURITY CLASSIFICATION. Enter the overall security classification of the report. Indicate whether "Unclassified Data" is included. Referring as to how it compares with appropriate security regulations.				
3. GROUP. Administrative Assigning as specified in DOD Directive 5200.23 and General Farago Instruction Manual. Enter the group number. Also, when applicable, show the specific markings have been used by Group 3 and Group 4 as indicated.				
4. REPORT TITLE. Enter the complete open title as all copies known. Titles at all times should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parentheses immediately following the title.				
5. DESCRIPTIVE NOTES. If appropriate, enter a type of report, e.g., review, program summary, annual, etc. Give the maximum dates when a specific working period is concerned.				
6. AUTHOR(S). Enter the names of author(s) as shown on or in the report. Enter last name, first name, middle initial, if military, when and branch of service. The name of the principal author is an absolute minimum requirement.				
7. REPORT DATE. Enter the date of the report as day, month, year, or month, year. If more than one date appears in the report, use date of publication.				
8. TOTAL NUMBER OF PAGES. The total page count should follow standard pagination procedures, i.e., enter the number of pages containing information.				
9. NUMBER OF REFERENCES. Enter the total number of references cited in the report.				
10. CONTRACT OR GRANT NUMBER. If appropriate, enter the applicable number of the contract or grant under which the report was written.				
11. MIL & SEC PROJECT NUMBER. Enter the appropriate military department identification, such as project number, sub-project number, system number, task number, etc.				
12. ORIGINATOR'S REPORT NUMBER(S). Enter the originator report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.				
13. OTHER REPORT NUMBER(S). If the report has been assigned any other report numbers (either by the originator or by the sponsor), also enter these numbers.				
14. AVAILABILITY LIMITATION NOTICES. Enter any limitations or further classification of the report, other than those				
imposed by security classification, using standard statements below:				
1. "Qualified recipient may obtain copies of this report from DDCI."				
2. "U.S. Government agencies and contractors of this report by DDCI as far authorized."				
3. "U.S. Government agencies may obtain copies of this report Security free DDCI. Other qualified DDCI users shall request through"				
4. "U.S. military agencies may obtain copies of this report directly from DDCI. Other qualified users shall request through"				
5. "All distribution of this report is controlled. Qualified DDCI user, shall request through"				
If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.				
11. SUPPLEMENTARY NOTES. Use for additional or explanatory notes.				
12. SPONSORING MILITARY ACTIVITY. Enter the name of the departmental project office or laboratory sponsoring (funding) for the research and development. Include address.				
13. ABSTRACT. Enter a abstract giving a brief and factual summary of the document's substance of the report, even though it may not appear elsewhere in the body of the document. If over 1/2 additional space is required, a continuation sheet shall be attached.				
It is highly desirable that the abstract of classified reports be unclassified. Last paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as TS, GS, UC, or C.				
There is no limitation in the length of the abstract. However, the suggested weight is from 150 to 225 words.				
14. KEY WORDS. Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that as security classification is required, Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indicator of technical content. The assignment of links, colors and weights is optional.
